If the earthquake not only destroyed buildings but also groves and standing crops and utterly ruined the agricultural wealth of those provinces, as some have said, the prices of these products are bound to continue to advance until they reach a very high level. Therein is a hint to our Florida citrus growers, says the Jacksonville Times-Union.

Regarding the Manufacture.

Consul Arthur S. Cheney, who, with his wife, lost his life in the destruction of Messina, made a report under date of December 7, which was published among the daily consular and trade reports of the department of commerce and labor under date of January 23 last, the subject of which was Essential Oils in Sicily.

The manufacture of the essential oils of orange, lemon and bergamot usually begins in that district about October 15. Judging from Consul Cheney's report, it seems probable that a very great amount of these products was yet in store awaiting shipment and possibly a great quantity yet remained to be pressed from the fruit, most or all of which is lost to commerce.

About 75 per cent of the total exports of essential oils produced in Italy were exported through Messina, now a heap of ruins. The United States was the best customer for these products, Great Britain coming next.

Great Exports.

For 1907 the production of citrate of lime, one of these products, being a combination of lemon juice and lime, for export, was 23,000 "pipes" for Calabria and Sicily. It was calculated that the yield of citrate of lime for the year ending October 31, 1908, was 20 per cent greater. As it requires 100,000 lemons to make one pipe of this oil, a pipe equaling 671 pounds, and about one-third of the lemon crop is used to make by-products, it is calculated that the crop of lemons for these two provinces was 6,900,000,000 in 1907.

There is no means of estimating the number of oranges and bergamots produced. The world's supply of oil of bergamot came from a comparatively small part of Calabria, in the extreme south of the mainland of Italy, and this experienced the worst effects of the earthquake. None were grown in Sicily, only six miles distant. The season for expressing this valuable oil had only just begun at the date of the report, three weeks before the earthquake.

Stocks of oil from the previous season were very restricted and the tendency even then was toward higher prices. Oil of bergamot is largely used in the perfumery trade. To obtain two and a half ounces of it, 100 bergamots are used.

It will be seen from the market report quoted above that it was selling for $2.92 to $3.70 a pound at the beginning of this year, and a greater advance was expected. The bergamot is a small, roundish orange, of fine flavor and taste, it may be explained to those not familiar with it.

Uses.

Sweet orange oil is, or was, produced in both Calabria and Sicily, but nearly all the bitter orange oil came from Calabria. The amount produced has depended upon the demand for fresh oranges. In seasons when the demand for fresh oranges was particularly good, very little oil was produced.

Citrate of lime is largely used in the manufacture of citric acid. Oil of lemon, expressed from the skin, is largely used by confectioners and pastry cooks for flavoring and in the manufacture or extract of lemon.

Uninteresting, perhaps, except to the growers of citrus fruits, yet these facts point to a demand for by-products of these fruits which are now neglected. Culls and fruit generally which cannot be profitably shipped can yet be used without loss in the production of the products mentioned above, products now commanding a high price and likely to go still higher. The rinds of citrus fruits, used in preserving or making marmalade, may be valuable for their essential oils, instead of being waste products.

May Manufacture in Florida.

It may be that the colony of Calabrians and Sicilians proposed for Manatee county, if they are admitted to this country, may go into the culture of the bergamot, with which they are familiar. If the foundation of that colony is frustrated, it may yet be worth while to turn attention to its culture in Florida.

At all events, there will certainly be a strong demand in the markets of the world for citrate of lime and the oils of bergamot, lemon and oranges on account of the destruction wrought by the earthquake of December 28, 1908.—Florida Fruit and Produce News.

DESTRUCTION OF CONCRETE BY ALKALI.

Cement has been found so generally serviceable and beset with so few disadvantages that its use is generally recommended without any reservation, and this confidence has been fully justified with but few exceptions.

Dr. W. P. Headden, chemist of the Colorado Experiment Station, has found serious injury to cement tiles from alkali. He reports as follows:

"There were sent to me, some months ago, a number of fragments of tiling which had been laid but from eight to nine months. They had been disintegrated to such an extent that one of the samples was simply a white, putty-like mass mixed with sand. There was nothing about this sample remotely suggestive of concrete. Another of the samples consisted of a fragment of the tile, the interior portions of which had been wholly decomposed, while there still remained an outer and inner portion in good condition, or comparatively so. Another sample had been attacked on the inner side, leaving the mass of the tile outside of the zone of decomposition apparently sound. The line of decomposition was sharply limited and showed distinctly, but even in this case there remained a thin layer of cement on the inside.

"I do not know whether the tile were running full of water or not; probably not, as the fragments seem to be parts of 16 or 18-inch tile. The importance of this point is simply this, that it would answer any question in regard to the separation of solid 'alkali' salts on that portion of the tile above the water line. That such a separation of these salts should take place does not seem very probable in this case.

"The point of attack, so far as the samples at my disposal indicate, is either in the center of the cement mass or near the inner surface. In either case we are almost compelled to assume the action of the water, i. e., of the salts held in solution. At the same time we see the resisting power of the outside and inside surfaces, which are evidently richer in cement than the inner portion of the mass of the tile."

Prof. Bioletti of the Viticultural Department of the State University demonstrated vine pruning for the benefit of vineyardists of Yuba City.

Live Stock and Dairy

Dairymen and stockmen are requested to write of their experience. Mrs. Sherman is always willing to answer queries and this, with experience of other workers, will make this department of greater value.

By Mrs. Minna E. Sherman

HOG CHOLERA.

THE losses from hog cholera in the states annually amount to millions of dollars. The spread of contagious diseases throughout the central stock yards and by cars and boats not disinfected—a condition which existed prior to the establishment of inspection by the Federal Bureau of Animal Industry—resulted in the contagious diseases existing in this country (among them hog cholera) becoming widespread, writes B. F. Kaupp, Pathologist, Colorado Agricultural College.

By the establishment of Federal inspection, in 1891, hogs were no longer allowed to be shipped back to the country after being unloaded in the central markets of Chicago, St. Louis, Kansas City, Omaha, etc., but on the other hand, were required to be sold for slaughter. The reason for this was that the yards were infested with hog cholera.

All cars containing hogs, as well as other animals, are inspected as the trains arrive at these markets, and those cars which contain cholera hogs, or any other contagious disease, are thoroughly cleaned and disinfected. Thus, through the careful, watchful eye of the Government, hog cholera has ceased to spread so rapidly.

Other means of spread that affect the local places are as follows: A dog running through a hog yard in which cholera hogs are kept will carry the germs on his feet. A neighbor, just to be neighborly, goes over to sympathize with a friend, and, tramping around on the infected ground, carries the germs home on his boots, and thus his hogs become infected.

In regard to treatment, the first measures should be a thorough cleaning up of the house and the yards. The hog troughs should be kept thoroughly clean and disinfected. The task of thoroughly disinfecting the hog houses, yards, troughs, and fences is not an easy one, but the free use of a spray gun with five per cent carbolic acid will be effective. Bichloride of mercury, one dram to each gallon of water, or creolin, one per cent, will do much good in the way of disinfection.

Medicines which are given by the mouth or in the feed or slop, are of little or no value. Many so-called "hog cholera cures" are put on the market, but they are fakes, pure and simple. It is an easy matter to get testimonials. Pacification of the mind may do as a "placebo" for the human mind; but if your hogs get cholera, they will need something other than medicine by the mouth.

There is one method of producing immunity against hog cholera, and that is by the serum injection. For many years after the discovery of the Bacillus Cholera Suis, the manufacture of hog cholera serum was attempted by the United States Department of Agriculture, through its Bureau of Animal Industry.

This serum is made by hyperimmunizing the hog by taking one that has passed through the disease and injecting this pig with a quantity of virus from a hog sick with cholera, and in this way producing in this hog a greater resistance, and as a result the serum from the blood of this hyperimmunized hog will produce a greater resistance against the disease in another individual and make it proof against cholera.

The Bureau of Animal Industry has been conducting extensive experiments along this line in Iowa for several years and has perfected this method of treatment. They have asked the Experiment Stations of the various states to co-operate by establishing the hog cholera experiment departments upon their farms so as to manufacture and furnish, at a minimum cost, all serum needed within the state. The serum, perhaps, costs a trifle more than those serums which can be produced by using the horse, as the hog does not furnish a great deal of blood.

MILK SICKNESS OR TREMBLES.

For the past four or five years complaints of the sickness and death of stock have been received from certain parts of the territory, particularly the Pecos valley in and around Carlsbad, and accompanying these complaints have come specimens of a plant which was supposed to be the cause of the loss. The losses were not confined to one kind of stock, but cattle were most frequently affected. The plant accused of causing the trouble (the ravless goldenrod—Isocoma heterophylla) had never before been accused of being poisonous, but the complaints against it were so uniform and continuous that they were believed to be well founded. The disease was believed by some to be due to "alkali poisoning" and was called by this name or referred to as "trembles," "slows," or "tires," depending somewhat upon the symptoms of the individual animal.

The financial loss arising from this cause was considerable; but, what is of much more consequence, there is a disease of man which occurs associated with that of the cattle and a number of cases of severe illness and a few deaths have been reported from the seat of the cattle disease. Doctors prescribing for the human patients diagnosed the disease as "milk sickness," the source of the trouble evidently being the milk of affected cows. This disease is one which prevailed more or less extensively in the central states during the early settlement of that part of the country, and is reported occasionally from the less thickly populated parts of that region even today. The true cause of the disease has never been ascertained until quite recently.

Through the efforts of various individuals more or less concerned, special investigators, Drs. Edward O. Jordan and N. M. Harris, professor and assistant professor of bacteriology, University of Chicago, were interested in the matter, went to the seat of the disturbance, and made an extended investigation of the disease. Autopsies of cattle in various stages of the disease were made and detailed examinations were made of all the organs of the affected animals and records kept of the conditions found in each. Two human patients suffering from the disease were seen. The result of their investigation led them to the conclusion that the disease is caused by a specific bacterium which they have called Bacillus lactimorbi.

So far nothing has been done in the way of remedial measures and the way in which the bacterium enters the animal is not certainly known though it is probably obtained in the food. Whether any particular kind of food is more liable to contain it than others is not known and the investigators are particularly anxious for more data which may reveal some method of preventing the entrance of the bacteria. Doctors who may meet with cases of this disease in their practice are requested to notify either of the above mentioned parties of such cases. A preliminary statement of the work which has already been done by these eminent bacteriologists was published in the Journal of the American Medical Association, May 23, 1908, which should be consulted, especially by the medical profession, for further information on the subject.

The symptoms of the disease in cattle are as follows: At first there is a noticeable desire to lie down, accompanied with loss of appetite. If

forced to run, the animal is usually seized with a fit of trembling, and if urged too far will fall. Generally there is marked constipation, and there is great weakness. The animal usually dies quietly, the breathing becoming fitful and weaker until death occurs. Some ranchmen report that a treatment which keeps the bowels open (such as doses of linseed oil or feeding Kaffir corn or similar loosening feed) has proved beneficial. —E. O. Wooton, Botanist of New Mexico Experiment Station.

DANISH CO-OPERATIVE CREAMERY

From the report of Manager J. R. Murphy of the Danish Creamery Association of Fresno we note the following:

The creamery has never before been on as good a financial basis as it is at present. While the price paid for butter fat in 1908 was not as high as the previous year, the amount of business was much greater as the secretary's report shows over one million pounds of butter made, besides over $14,000.00 worth of cream sold.

We have now twelve wagons gathering milk and cream covering a territory of about twelve miles square. We have two wagons delivering butter and cream in Fresno. One double team, and one short order wagon. There is hardly a train going out of Fresno that has not a shipment of Danish Creamery butter for some of the towns throughout the valley. We are supplying about one hundred and twenty-five grocery stores in this valley with butter besides what is shipped to Los Angeles and other outside points.

The average person uses about half a pound of butter a week, so that there are about twenty-five thousand people with Danish Creamery butter on their table every day of the year.

The prospect is very flattering for the dairy business next year. The supply of cold storage is all gone, and I can see no reason why the present year should not be a prosperous one for the dairyman.

The demand for good butter seems to be increasing all the time. I predict a great future for the dairy business in this valley. We are in a business that is able to take care of itself and we are not concerned as to whether a low or high tariff rules.

Fresno county produced over 3,000,000 pounds of butter last year and the value of her dairy product was over $1,500,000.00. The day is coming when the raisin man will have to take off his hat to the great dairy business of Fresno county.

Mr. E. G. Webb, connected with the same creamery and proprietor of El Guernsey Rancho, writes in connection with the same report: "The present high price of food should make the dairyman get down and study as to which cow is paying profits. If he does that he will soon realize that only good cows pay."

AYRSHIRE BREEDERS' ASSOCIATION.

The 34th annual meeting of the Ayrshire Breeders' Association was held at the Manhattan Hotel, New York, on February 3rd, 1909, with about fifty members and others present.

The Association voted $300.00 each as special premiums for Ayrshires shown in the ring at the Alaska-Yukon-Pacific Exposition, and the National Dairy Show for this fall.

The officers elected for the ensuing year were: E. J. Fletcher, Greenfield, N. H., president; J. F. Converse, Woodville, N. Y., vice-president; Geo. E. Pike, Gouverneur, N. Y., vice-president; J. W. Clise, Seattle, Washington, vice-president; J. A. Ness, Auburn, Maine, vice-president; C. M. Winslow, Brandon, Vt., secretary and editor; N. S. Winsor, Greenville, R. I., treasurer; W. P. Schanck, Avon, N. Y., Executive Committee for three years; Howard Cook, Beloit, Ohio, Executive Committee for three years.

A new condensed milk plant is being erected at Ellensburg, Washington.

USUAL CROP OF CREAM SEPARATOR SNARES AND TARES

If actual merit alone prevailed the DE LAVAL cream separator would be the only one made, sold or used.

But the dairy farmer with his dollars is an alluring proposition to those who "need the money," so that every season brings with it a new crop of separator fakes and fables, with some of the old conjurers over again and always a few fresh ones.

Last year the new and improved line of DE LAVAL machines literally swept the field. This year everybody has a "new" machine, which is the one thing they universally harp upon in their talk and advertising. But it is mostly bosh and nonsense. There is mighty little new to them. No more DE LAVAL patents have expired so that there is nothing else "new" that they can lay hold of this year.

There's the usual crop of fakirs appropriating the facts of DE LAVAL separator use and the endorsements DE LAVAL separators have received, and quoting them as though they applied to their own inferior imitations of the standard cream separator.

There's the concern which makes an inferior disc separator and speaks of the "disc" separator being "the machine which has won out universally in Europe, the home of the disc separator." True, but it was the DE LAVAL that has done the winning out in Europe, as it has in America.

There's the political separator concern, with the new "year" or "cents" trademark, whose claims it is to be hoped nobody ever believes, and which manifestly practices the circus man's theory that the great American public ever likes to be fooled.

There's the only concern which has stuck to the abandoned DE LAVAL "hollow bowl" of 30 years ago, but will this year desperately join the procession of 10 year back DE LAVAL imitations with a "disky bucket bowl" machine.

There's the "Trust," striving to complete its monopoly of dealer and farmer, harvesting much costly separator experience, largely at the expense of buyers-for-use, through trying to build a cream separator like ordinarily made farm machinery.

There's the "mail order" outfit, with their cheaply made machines, bought here and there, not made by themselves or sold under the real manufacturer's name, all claiming the earth, and many of the things that should be below it.

But the merry lot changes and dwindles every year. They gradually drop out and leave their unfortunate patrons helpless with trashy machines. More will fade away this year. The dairy farmer, like the creameryman, is coming to know something of separators. He doesn't swallow mere "claims" so easily. 98% of the world's creamerymen use DE LAVAL machines. The percentage of farm users content with nothing else is always increasing.

There isn't a single reason why every man who buys a cream separator this year should not buy a DE LAVAL. There are many reasons why he should. The best costs no more than the various grades of inferior imitating machines.

A DE LAVAL catalogue may be had for the asking. A DE LAVAL machine may be tried for the asking.

GREAT IS THE ORANGE.

The surprising growth made by the citrus industry of California has been remarked upon in the editorial columns of this paper many times. An industry which was regarded but a few years ago as the fad or play-thing of the wealthy has become today the greatest of wealth bringers to this state. The railroads alone are reaping more than a million dollars every month for transporting the golden apples to market. We do not know that there are any statistics which would show the amount of land covered in the growing of California oranges, but as a rough guess we may say that in bearing trees there is at least in excess of 100,000 acres. This in comparison with the vast expanse of farming land gives a faint conception of this state's possibilities when all its lands are given the same intensive cultivation that is required by the orange grove. Of course it cannot be that every acre of tillable land in California can be brought to the wealth-producing condition of an orange grove.

But to one who looks at the great possibilities of the state it is an encouragement to know what has been done with this industry. The writer well remembers but a few years ago when the productions did not exceed a million boxes, and that the market conditions were such that the utmost discouragement prevailed. Through co-operative marketing such encouragement was given to the industry through honest returns secured for the producers that the production of that time has been increased more than twelve fold; or as usually referred to in carloads, the state is today producing nearly 30,000 cars of oranges and perhaps 5,000 cars of lemons. A car is usually considered to consist of 366 boxes of oranges. Of this vast output of oranges the section south of Tehachapi will produce over 25,000 cars, Tulare county section perhaps 2500 or 3000 cars, Fresno county 200 or more cars, Butte county perhaps 1200 or 1500 cars more. There is scarcely another county in the state but can produce a few for local consumption.

To be more particular we may be permitted to take some figures which were secured some months ago by the Riverside Press as to the production for the coming year. This shows that the Redlands district, including Crafton, Mentone and Redlands Junction, will produce this year 4350 carloads; Riverside district including Highgrove and West Riverside, 4225; Pomona, including San Dimas, Lordsburg, and Claremont, 2350; Ontario-Cucamonga, 2350; Highland, 1650; Azusa-Glendora, 1575; Covina, 1350; Rialto, 950; Alhambra-Pasadena-San Gabriel, 900; Fullerton, 900; Orange, 750; Colton, 575; Corona, 525; Duarte-Monrovia, 525; Whittier, 745; Ventura, 310; San Fernando, 250; Moreno, 200; San Diego county, 150; Anaheim, 135; Hemet-San Jacinto, 70; other localities of Southern California, 435 cars. This with the five thousand cars from north of the Tehachapi runs into an aggregate figure which is almost inconceivable. To this must be added again 5000 cars of lemons sent from south of the Tehachapi.

One thing needful in this great industry to make it more profitable and to completely utilize it as a wealth producer is to establish factories which will turn the waste products into gold coin. In Italy and its islands the cull fruits which are here returned to the orchards, or often, worse, hauled off to the "wash" and thrown away, are used in the production of acids, oils, or other valuable products, which gives labor to many and brings to the producer of the lower grade fruit some little return for his product. There have been some efforts in this direction and at Riverside there has been quite an output of a high grade marmalade, and efforts are now being made for the establishment of a vinegar and orange wine factory. The manufacture of candied orange peel has been attempted but never put upon a large commercial basis. Another industry attempted has been the candying or preserving of the citron. A very fine product has been put out but more economical methods of work are needed to make it a success.

When these steps can be taken and this added to the income of the already prosperous industry we are safe in predicting a greater future for this industry.

DUE TO CO-OPERATION.

To no factor so much as that of co-operative marketing is due the prosperity outlined in the above article. In 1890 it was practically impossible for the orange producer to get even courteous treatment from the larger packers and commission men. The outwardly polite invitation to "send your fruit to us and we will do the best we can for you" fell upon the ears of the producer with a sickening thud. And the returns which came at the end of the season were not such as to cause any more cordial feeling than at the beginning of the season. Growers felt absolutely helpless, and in fact were, until they determined on co-operation in the selling of their products and determined to form and take up the plan as a last and almost forlorn hope. We say forlorn, for the reason that there had been former efforts along the same line by the grower, only to find himself steered into the arms of the smiling commission man and to find himself as before fleeced in the final transaction. Fortunately the new movement fell into the hands of competent and honest people and the money which the fruit secured in the market after being more intelligently distributed than it had been for years, was turned over to the grower. This was not all accomplished at once for errors were made, financial losses came which caused some discouragement and many to forsake the movement which was organized for their salvation. But as years passed and the experience of marketing gave greater wisdom to the growers better returns were secured and today the California Fruit Growers Exchange stands without a peer in the world as a success in co-operative marketing of farm products.

This great organization received for its members and turned over to them last year the vast sum of over $12,000,000. This $12,000,000 was turned over to about 4,000 members. These 4,000 growers own or control in excess of 65,000 acres of orange groves. These 4,000 members are organized into about 100 associations. Each association owns its own packing house and equipment, some of them having assets of this kind aggregating many thousand dollars. These hundred associations are organized into 14 exchanges or selling agents, which in turn deal with the great central organization with its offices in the H. W. Hellman Building, Los Angeles. Notwithstanding this great business aggregating $10,000,000 to $12,000,000 per year, the past four years have shown practically no financial losses owing to non-collection of accounts.

The greatest asset perhaps of this association at the present time is the good will of the entire eastern trade, which has been secured through square dealing and the putting out of honest goods attractively packed. Besides this it has the good will and entire confidence of the producers who are standing by it stronger today than ever before. Sixty-five per cent of the citrus output of the state will be in the hands of the Exchange this year.

ADVERTISE.

On first page of this issue of the Cultivator may be seen a reproduction of the advertisement of California oranges which at the expense of many thousands of dollars was inserted in a vast number of papers all over the middle west about the first of the present month. It was to advertise "orange week" which California Fruit Growers Exchange established for the purpose of calling special attention to California citrus fruits. It is gratifying to know that the people of the East entered into the spirit of the request made through these advertisements and the dealers found themselves busy waiting upon people who were anxious to buy "Sun-kist" oranges.

This is not the first effort at advertising which this organization has taken up, for last year a try out was made of the state of Iowa with a similar campaign. This year the field was greatly extended and we doubt not the results will demand of the same organization still greater extension another year. We believe the lesson of this successful advertising campaign may well be taken up by producers of other products in this state. We believe that had the raisin growers combined and used their means to advertise luscious California raisins, then pushed their product on the market at the very highest possible price to be secured without effort to combine on a price, that the entire hold-over crop would before this have been disposed of.

FIGHTING THE PESTS.

California orange growers have not only co-operated to sell their products, also to buy supplies, but are today co-operating in the fighting of insect pests which have sapped the life from many groves. This movement was started in Highland, which boasts that as yet it has none of these pests to fight but organized its growers into this movement as a means of protection from encroachment. Its main features which are outlined in another column of this issue appealed to growers of other sections so strongly that similar efforts are being made to bring the growers together for a mutual fight on all sides.

The list of these injurious insects seems to be increasing every year. Of course it is possible that the natural enemies of these pests will arrive, as they have in some cases in the past, but intelligent co-operation in studying this problem will in no way interfere with the introduction of their natural enemies.

DEATH OF RACE TRACK GAMBLING.

The anti-race track gambling bill over which the better element of this state has waged a warfare for years and which was finally passed by an overwhelming vote in both Senate and Assembly was at almost the last moment signed by Governor Gillette. This bill has been watched closely by its friends and we are assured without question it will stand the tests of the highest courts. It will sound the death knell of gambling on horse races in this state and we trust encourage other states in taking similar stand.

Governor Gillette's action in this matter in delaying his signature as long as he did and in refusing to send a special message to the State Legislature touching upon it, is such as to cause regret on the part of all well wishers of the state. In this respect it has been in marked contrast with the action of Governor Hughes of New York.

Agricultural Notes of the Pacific Coast

Northern California

San Leandro is planning for a cherry carnival to be given when the cherries are ripe.

Wool buyers at Ukiah admit that wool will probably reach the 25 cent notch in the next few months.

Farmers in Modoc county claim that grass is further advanced in its growth than for years at this date.

Pres. Rossi of the Italian Swiss colony, Sonoma county, announces that the wine market is much improved.

Owing to the $5 per ton price offered by the Alameda Sugar Factory this year liberal plantings of beets are being made.

E. K. Carnes, in charge of the State Insectary at Sacramento, is experimenting with a new black scale parasite received from China.

The crane fly is doing much damage damage to some sections of the Sacramento valley last year is again reappearing and injuring growing feed.

It is now estimated that not over 50,000 sacks of potatoes were lost during the floods on the islands of the Sacramento and San Joaquin rivers.

A coyote hunt has been organized in Marysville to rid some of the farming sections thereabout of coyotes which had destroyed much young stock.

The Horticultural Commission of Solano county is keeping close tab in imported nursery stock and has prevented the introduction of many pests.

Horticultural Commissioner Stabler of Yuba City has discovered a shipment of vines into the county which were infested with Phylloxera. They were promptly burned.

January rainfall at Vacaville aggregated 15.18 inches. This is greatest of any year the record was kept there since 1887. The only other year it approached this amount was in 1896 with 15.06.

The Harbor Board of San Francisco, in charge of the San Francisco Free Market, has notified tenants of an increase in the rate charged because of failure to provide funds sufficient to cover the expense under the old rate.

Six millions of eggs in one incubator would be a great record indeed. In fact in a sense that is what is being accomplished at the State Fish Hatchery at Grizzly Bluff, there now being over six million fish eggs in all stages of propagation.

The creamery at the State University Farm at Davis has paid its patrons about Davis for cream for the five months ending the first of the month $5,208. The creamery is primarily for the work of education but incidentally the cream has to be bought and is marketed so as to return the dairymen the above sum.

Sebastopol berry growers have formed a corporation known as the Sebastopol Berry Growers Incorporation. The capital stock is $5,000 and each member must own at least one share and not more than five, averaging $10 each. The officers of the organization are: W. I. Newcomb, president; W. M. Hotle, vice-president; Ira G. Hambleton, secretary.

Central California

The General Grant National Park in Tulare and Fresno counties is four feet deep in snow.

Porterville real estate is proving quite active, several pieces having been sold at good prices during the last few weeks.

The work of the Horticultural Demonstration Train has been successful in bringing information to many farmers throughout the valley.

August 24 has been set apart as San Jose Day and August 20 as Porterville Day at the coming Alaska-Yukon Exposition at Seattle.

Several bunches of hogs brought in from mountain ranges where they have fattened on acorns near Porterville netted five cents per pound.

The ten cent increase in dried fruit transportation it is feared will have a serious effect upon the marketing of low grade hold over fruit yet in hands of producers.

The Kings County Farmers Union at a recent meeting objected seriously to the moving of the state headquarters of the Farmers Union from Kingsburg to Fresno.

The effort of Tulare county people to secure a fish hatchery will fail, it now appears, as the Fish Commission maintains that the hatchery located in Siskiyou county is ample.

Another raisin selling plan has been proposed by one of the largest packing companies in the San Joaquin valley, which is a makeshift but may possibly succeed in unloading the past year's output.

Creamerymen the state over are taking more interest in making butter with a lower per cent. of water than formerly since the recent arrests because of butter containing more than 16 per cent of moisture.

The recent election of the Turlock irrigation district resulted as follows: T. A. Owen, A. Hallner, E. P. McCabe to act on the Board of Directors; E. B. Osborn of Turlock, treasurer; Joseph Cross of Ceres, assessor and E. W. Brush collector.

W. Q. Dale, a dairyman of Stanislaus county, has a Holstein cow which in 100 days yielded him 6,744 pounds of milk containing 216 pounds of fat. This cow returned to its owner almost $1 per day for the hundred days, besides the $75 which he received for her calf.

At a recent meeting of the Santa Clara County Patrons of Husbandry the Sempervirens Club, and the Native Sons, a joint committee was appointed to proceed to Sacramento and appear before the legislative committee in the interests of the Big Basin Redwood Park. All worked against the retaining of State Forester Lull.

Cattlemen of Bakersfield who were caused heavy loss by large numbers of the cattle being killed by the Humane officers of Los Angeles when being transported through that city, are indignant and claim the slaughter was entirely unnecessary. The Humane officers of Los Angeles, however, maintain that the stock were practically being starved to death and so weak that many of them were unable to get up when once they were down.

Southern California

Redlands has shipped about 1200 cars of oranges this season.

Orange picking is again in full swing after the forced vacation during the storm.

The Richland Walnut Growers Association of Orange recently met and adopted by-laws.

Berrydale in Orange county is promised a big season in small fruits and vegetables.

Oranges are now going forward rapidly, crowding up close to the 200 cars per day mark.

Escondido is planning an organization to conduct a county fair to be held in September.

Last week was orange week in many of the towns and cities of the East and Middlewest.

Nearly all nurseries of Southern California have been sold out on orange and lemon trees.

Orange prices so far received compare favorably with those received last year up to this date.

Poultry raising is becoming more popular at Beaumont, several new ranches being started this season.

Artesian wells of Southern California are all flowing more water than for some years at this time of year.

A corporation is being formed with a capital of $50,000 at Santa Ana for the purpose of establishing a new creamery.

Riverside Groves and Water Company is laying out an 8,000-acre tract at Arlington, which will be subdivided into small homes.

Coachella cabbages are going forward and commanding good prices, the last sale being in the neighborhood of $41 per ton.

A large orange packing house at Redlands Junction, San Bernardino county, has recently been sold to the Denman Fruit Company.

Beaumont has organized an Eucalyptus Club and started to secure a fund of $5,000, which will be used in the planting and caring for eucalyptus trees.

The Carpenter and Serrano Water companies of Orange county contemplate the building of another large storage reservoir which will cover about 70 acres.

Many Southern Californians are interested in the bill before the State Legislature which proposes to reduce the number of County Horticultural Commissioners from three to one.

Prices of lima beans received by the grower this year were nearly one cent lower than those of last year. But at present the market conditions are very materially better than for several weeks.

The improvement of the famous Magnolia Avenue is the object of the Magnolia Avenue Improvement Association of Riverside, and it is hoped that it will be macadamized and otherwise greatly improved.

Oxnard is constructing a miniature representation of her sugar factory, to be used as a part of her exhibit at the Alaska-Yukon Exposition. Another feature in the same exhibit will be a small bean thresher turning out quantities of lima beans.

The Coast

The Trans-Missouri Dry Farming Congress convenes in Cheyenne this week.

The Phoenix Republican says that the Wilson district near that city is becoming noted as a chicken and egg producing section.

A thousand bushels of bluestem wheat was sold in Walla Walla, Washington, at $1 per bushel.

An effort is being made in Arizona to secure the early enactment of a territorial dairy inspection law.

The streets of the city of Tempe and the roadways leading to the country from that place are being improved by walks and planting of shade trees.

The farmers of Idaho, Oregon, Montana and Washington are all urging their representatives in Congress to stand pat on the matter of protection of farm products.

California floods have been the means of material increase in the price of potatoes at Portland, prices now ranging for good potatoes from $1.15 to $1.25 at country points.

Contracts are already being made for the spring clip of wool at Lewiston, Idaho. Prices are kept secret, but rumor has it that they are in the neighborhood of 20 cents per pound.

It is estimated that 5000 acres of sugar beets have been planted for the factory at Glendale, Arizona. The factory is now being repaired and enlarged to handle the increased acreage.

Cheese factories at Tillamook, Oregon, are forming an association which will have an inspector to examine and pass upon all the cheese manufactured by members of the association.

The stock men of Idaho have as a rule endorsed the action of the Forestry Service in the management of the reserves, this notwithstanding the action of the National Wool Growers Convention.

The extreme cold weather which has visited Idaho has done some injury to the peach orchards, but the claim is made that the injury has only been sufficient to make unnecessary any thinning of fruit.

The Beaver Head forest reserve is now thrown open by the Secretary of Agriculture for grazing, and 29,000 head of cattle and horses and 110,000 head of sheep are expected to fill the reserve the coming season.

Territorial Fair Commission of Arizona is being reorganized by Gov. Kibbey. He has requested the resignation of one of the old members and it is rumored that the big stockman Dwight B. Heard will receive a place on the commission.

Much discussion is being had in the Hawaiian Islands as to the wise use of her public lands. An advisory land law commission is advising certain changes in the administration of these lands which it is hoped will be beneficial to the country.

Sheep owners near Hu[illegible] Washington, are planning for a gr[illegible]nd up of coyotes. The effort will be to have the drive extended over a great part of the two counties of Klickitat and Wasco, Oregon, as well as in the immediate vicinity of the drive.

Deciduous Fruit Culture

By J. W. Mills

ROOTING GRAPE CUTTINGS.

IT IS not necessary to make grape cuttings longer than twelve inches, when planting in nursery form or in the vineyard. It must be remembered that the part that sticks above the surface of the ground is constantly drying out with no root to supply the moisture.

Cuttings with the bottom end near the surface will strike root quicker than when planted deeper. It used to be the general practice to use long cuttings and plant them at an angle so as to get the lower ends near the surface. This is a useless practice, and very undesirable because it makes a crooked vine. Why not make the cuttings short enough to have the top buds at the surface of the ground and the lower ends close enough to the surface to give them the proper amount of warmth and still keep them perpendicular. The vines will then be as straight as little nursery trees.

If the cuttings are planted on heavy soil, or that which is liable to crust, the ends should project two or three inches above the surface to prevent them becoming filled with water or mud. It may have a bad effect on the top buds. There should always be enough of the cuttings projecting above the surface to enable the men to clearly distinguish the rows. This is in the nursery rows. When cuttings are planted in vineyard form, each one should be staked.

In heavy clay soils, it is useless to plant cuttings deeper than ten inches or a foot, for they will rot off. This is especially true in the Imperial valley and in that region all the projecting top will dry out and die down to the bud below the surface. That is the general result.

The surest way to get a good stand of cuttings is to tie them in bundles of about 200, place them in a trench with good subdrainage, bottom ends up and cover with about four inches of sand or sandy soil. The warmth will start the roots very soon. When the callous begins to form, take them out carefully, place in a box with moist dirt in the bottom and keep covered with a wet sack while placing in the ground. The soil in which they are to be planted should be loose enough to allow the cutting to be pushed down into it without bruising the tender callous. The soil should be settled around the cuttings with water within a few hours after planting.

If the air comes in contact with the sand that is placed over the ends of callous as freely as recently loosened soil will permit, many of them will die. For the same reason the soil or the cuttings during the callousing process must never be disturbed unless immediately settled with water. It also should never be allowed to become dry.

A convenient method of making neat bundles of cuttings so as to have the lower ends of the cuttings all even, is to cut them in a box. Place a wire down the sides and across the bottom about six inches from the end of the box furthest from the operator. Place the butt end of the cutting against the end of the box and cut it the right length with shears. The cuttings will all fall into place and when the box is full to the top, bring the ends of the vines over and twist tight. The bottom ends of the cuttings will be as even as though they had been sheared.—J. W. Mills.

SMALL CANNERY.

In reply to a query as to starting a small cannery, Mrs. M. E. Sherman writes:

The proper way to estimate the size of a cannery is to count the number of cans to be filled each day. If the crop of fruit to be put up is one hundred tons and time fifteen days, by roughly estimating forty cases to a ton of fruit, and twenty-four cans to a case, weighing two and a half pounds to the can, it amounts to about 6400 cans of fruit to be peeled, packed and cooked each day.

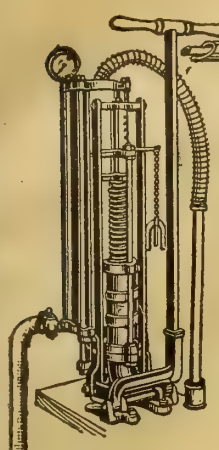
The cook room capacity therefore governs the cannery's output. The buildings need not be expensive, sheds answering, but the floors must be good well-matched stuff or they cannot be kept clean. A large boiler to furnish the steam for cooking the fruit must be provided with a dome to give dry steam. The fruit is cooked in the cans by swinging the small baskets holding a dozen cans each into the larger basket, that is handled by an overhead crane or a track. These cranes carrying baskets run along to the large wooden cooking vats and are let down into the water. The bottoms of these vats are furnished with pipes connected with the boiler and the fruit cooks by the heat of the water around it. It is a furious boiling they get from the hot steam. A syrup room is built overhead where the syrups are made of the different densities called for by the various grades of fruit. The syrup tank is also fitted with steam pipes for cooking. Syrup runs in pipes to a machine in the cook room just below it. This machine fills a basket of the cans at one time. As many machines as are needed increase the rapidity of the operation by filling a larger number of cans at one time.

The cans are then capped and left with the blow holes open. The capping machines solder the cans quickly. After the first cooking the cans are lifted by the cranes, the small holes quickly soldered up—"dotting" this is called. Then the fruit is let down into the water again and receives the second cooking, "processing," this is much longer than the first one. In large plants this work of handling is done by a belt that moves the cans from one place to another, and into the cooking vats and out of them. There is much detail in running a cannery successfully, and the margins of profit come in saving half cents on a case in the different processes. It is necessary to have a good training along the lines from the special and complicated forms of book-keeping to the understanding of the system of checking up the labor daily. In installing a new plant of this small size much of the outfit could be second-hand. There are promoter canneries going up all the time that do not run for more than a season, whose outfit can be purchased reasonably.

It is interesting work running a cannery. I love to be on the floor with the women and, at night, dream I hear the flute like voices calling "Fru——it! Ca——ans! Boo——xes!" As the peeling and pitting is piece work the prices are governed by that paid by the other canneries. The cook men are engaged by the hour. These men must be watched and they give more trouble than any other employees about the place. They must be kept going all the time and their time cards punched out when they come to a halt for want of fruit. This is one of the big leaks in the cannery, and the hardest to control. The packing house force begins at 6 o'clock and the cook house starts at 7 or 7.30 in the morning.

If the cannery is to work this season it is fully time to be making the contracts for cans. Labels the first season can be stock ones with the local name printed in. The American Can Company furnishes most of the cans used on this coast; they are located in San Francisco. The box shooks come in carload lots and the orange packers will tell the address of the mills that will furnish the stuff.

Every morning the book-keeper should tally up the tickets of the cutters and peelers with the amount of fruit that has gone over the scales, then tally this against the amount of fruit that has gone into cans and is now in the cooling shed. The manager goes every day to the pile of yesterday's canned goods and tests them. He selects personally a can from each grade and kind of fruit. White graniteware bowls are provided and each can of sample is cut



Saves One-Third the Labor

Wouldn't you like to cut your labor expense an even third? You can do it on your spraying —and this advertisement tells you how. What's more, the work will be done more quickly and better. Use

Bean Magic Spray Pumps

The Bean patent spring (shown in the cut), divides the work; the operator does half at each stroke of the handle, and works against but half the pressure indicated on the gauge. Bean Magics are built in two sizes; both have non-clogging ball valves, porcelained cylinders, and other exclusive Bean features. They're the easiest running, least troublesome pumps on the market.

Our illustrated catalog No. 21 describes ten sizes of hand pumps, and contains much valuable spray information and formulas. Catalog No. 22 describes Power Sprayers. Both books sent free. Write for our special offer; mention number of acres and kind of fruit.

Prop. Pleasant View Nursery.

and emptied into a bowl. First the number of pieces is counted to see that the grade is right, large fruit being of higher grade than the smaller pieces. The number in the cans, if correct, establishes the grading. If they are wrong, the can is looked at and the number of the girl that put that fruit into the can is taken and she is cautioned against making that mistake again; when it comes again in her work she is sent to the cutting table and another girl takes her place. The girls at the packing table are paid by the day and the work is liked better than the cutting and peeling. Then to return to the fruit. Examine the cooking, then test the syrup for density.

After the fruit has been examined it is turned into a can, more syrup put on it and it is stamped as a re-cook. The pile of yesterday's fruit is removed to the warehouse when cooled. As it is removed it is carefully looked over for leaking cans; if these are discovered they are stamped as re-cooks and go again through the vats to be heated up, then have the leaks soldered up. These re-cooks are not sold with the standard pack, but as a cheaper grade of goods.

This is all I can think of at present to tell you, but you can see that it is well to go to a good cannery as an assistant on a small salary before attempting to run one of your own. The watchfulness has to cover all parts of the work. It is worth learning to do it right, for right in your own plant you can earn $50.00 to $100.00 a week by staying at it. I never hesitate to keep two maids at the house, because I can put in my pocket in a few weeks each summer the wages they cost. In other words, the superintendence work in the packing house cannot be hired to make the profit the owner can make out of it. I believe either pack your fruit yourself or sell it outright for whatever you can get. The packing is poor when you are not right after it and even then, struggle as you will, it is often pretty poor.—M. E. Sherman.

GRAFTING WAX.

The best grafting wax is made from four parts of resin, two parts beeswax and one part tallow, all by weight, melted together over a rather slow fire in an iron vessel of some kind. The resin is melted first, then the beeswax is added, and subsequently the tallow. The ingredients are gently stirred with a small stick and thoroughly incorporated. This will take from twenty minutes to half an hour, being careful in the meantime to avoid burning the fluid. When properly mixed, a convenient portion —not too much—is poured into a bucket of cold water. In a minute or less it will be cooled sufficiently to be lifted out with the hand and pulled like taffy. The hands must be kept moderately greased with tallow, to prevent sticking. When the wax is pulled until it becomes pale yellow it has been worked sufficiently and may be made into rolls of convenient size—three or four inches long by about an inch in diameter—and placed in another vessel of cold water to harden. More of the melted material is to be poured into the cold water from time to time, and treated as before, until the whole is worked up. The rolls (when they become hard, as they soon will) are to be put away until required in grafting. This wax when applied to the trees will not crack in cold weather, nor melt and run down in warm weather. If grafting is done in cool weather, the wax may need to lie in warm water for a time before applying to the grafts, in order to have it of the proper consistency to work well; if used in warm weather it may need to lie in cold water. Care is needed in lifting it out to free it from the water as much as possible. In putting it on the grafts the hands must have a little—very little—tallow, to prevent the wax from sticking to them. This requires judgment, for if the hands are too greasy the wax will not adhere properly to the cut surfaces of the grafts. It should be pressed closely.—Journal of Agriculture.

TREE TANGLEFOOT

A Sticky Preparation Applied Directly to the Bark of the Trees

Will not injure trees. A band 5 inches wide and 1-16-inch thick cannot be crossed by any climbing insect pest. Remains sticky five to ten times as long as any other known substance. You can test it at slight expense, as no apparatus is required. Used by the carload in New England against the Gypsy and Brown-Tail Moths. In California it preserves prune orchards from the Canker Worm. Wherever the Gypsy or Brown-tail Moths, Tussock Moths, Fall or Spring Canker Worm or Web Worm appear TREE TANGLEFOOT is of great value, and should be used when the caterpillars begin to crawl while they are very young.

Price 25c per lb. Liberal discount on quantities. The only safe and effective banding preparation. Send for testimonials.

"Chicks Well Hatched are Half Raised."

San Jose Hatchery, San Jose, Cal.

ANNOUNCEMENT

We stand for strong, healthy chicks and will spare no efforts to secure them. Our aim is quality rather than quantity. From the eggs we hatch we want the best chicks that can be secured. We shall limit our capacity to 12,000 eggs—six of our 2,000 egg incubators.

Three factors in securing chicks are—the breeding stock for hatching eggs; the incubator and the man to do the work.

We take great care in selecting our breeders from which we secure eggs. The stock must come up to our standard. Our Mr. Langenschwadt attends to this. He is a practical poultryman.

The incubator we use has been tried out and demonstrated for several years past what it can do. We consider it the best we have come across so far. The success poultrymen are having with chicks it hatches is proof sufficient.

In Mr. Henry Langenschwadt, our manager who attends the incubators, we have a man whom we are satisfied understands his business and he is demonstrating this by results.

At present can furnish following breeds and shall add to them as we can secure stock. All from utility stock:

White Leghorns we hatch regularly in two grades—No. 1 and special. Will hatch lower priced to order but cannot recommend them.

No. 1. White Leghorns: $9.00 per 100; $25.00 for 300; $40.00 for 500; $75.00 for 1,000.

Special White Leghorns: $12.00 per 100; $34.00 for 300; $55.00 for 500; $105.00 for 1,000.

Brown Leghorns, $10.00 per 100. Black Minorcas $12.50 per 100.

Rhode Island Reds, $12.50 and 15.00 per 100.

Barred Plymouth Rocks, $12.50 per 100.

Lots of 50 add one cent each. Less than 50 chicks do not recommend to ship.

Address orders to **SAN JOSE HATCHERY,**
395 East St. James Street,
Henry Langenschwadt, Manager **San Jose, California.**

Special Prices

Today we have on hand a few of the latest models of the "Old Trusty" Incubator, just as long as they last you can have them at the lowest prices ever made by any Incubator company in the West. We wish to get our money out of them quickly, we will hold any machine you wish to select if you send a $2 deposit, these machines will not last but a few days at these prices. Now is the time to BUY and save many dollars while you can. This ad may not appear again. If you do not have the catalogue, 148 pages, send for it. We pay R. R. freight in Cal. 120 Egg Size, $10.90, 165 Egg Size $12.90, 240 Egg Size $15.90. These machines are all complete with all attachments ready to run.

Profit in the Poultry Yard

By Mrs. Frank Metcalf

We solicit short articles of a practical nature from the fancier and utility breeder, giving their experience with poultry. All inquiries pertaining to feed, management, disease and its prevention will be answered through these columns.

POINTS ABOUT PIGEONS.

PIN FEATHERS appear when the young are a week old.

In market squabs are considered too "hard" when they are allowed to fly about the pen before being killed; they are too "soft" when the skin of the crop and of the abdominal pouch is thin and transparent, and these parts are full and the heart undeveloped.

Pigeons are not destructive to gardens, as is commonly believed. Their beaks are not like that of the crow, to enable them to dig with, nor have they feet like the chicken to scratch with. Pigeons simply walk over the surface of the ground and pick up what is in plain sight, which consists principally of weed seeds.

When pigeons are "married," they remain true as steel, divide labor, are ever in each other's company, not attracted by "new faces," do not bother about their neighbor's business, and are always busy at their own work.

The older a male pigeon grows the more fatherly he becomes.

There is in fowls no affection so near the human being in its fine nature, as that of pigeons.

Owing to this intense affection, more birds are grieved to death by isolation than die from results of disease.

At a day old pigeons are known as "peepers;" at ten days old, "squeakers," and at three weeks old, "squealers."

A squab grows enormously the first twelve hours, and very rapidly after the third day.

When first born they are sparsely covered with long filaments of down the root of each filament indicating the point from which each future feather is to start. The down for a while still hangs on the tips of some of the feathers, during their growth, and is thought by some to be finally absorbed into the shaft of the growing feathers.

Pigeon manure weighs from thirty to thirty-five pounds to the bushel. It contains 3.20 per cent of nitrogen, one per cent of potash, and 1.90 per cent of phosphoric acid—about double the amount of these ingredients found in hen manure.

Should two young cocks select the same hen for a mate, they will engage in a deadly fight. Their method of carrying on a combat is peculiar. The beaks and wings alone are used, the rivals catching hold of the skin of the head with their beaks and beating each other with their strong wings.

Once in a great while a pigeon tires of his mate and seeks another. In such a case he meets with a vigorous protest from the companion of the bird which he covets. Should he persist in his attention, he is often attacked by the entire male element in the loft, and either driven from his home or killed outright.

Miller Purvis tells an interesting story: A breeder gave a pair of Homers to a friend, who took them home with him, fully fifty miles away. The birds were kept confined until after they had bred three pairs of squabs. They were then allowed their liberty, and were not out in the open more than an hour when the hen wanted to "go home and see mother," which she did. This so disgusted her husband that he left in another direction, got a new wife and brought her back to his new home, evidently as a sweet revenge on his runaway spouse.

Close observers have noticed that the hen pigeon during incubation, sits on the nest from 4 o'clock in the afternoon to 10 o'clock the next morning. The moment she leaves the nest the cock bird assumes duty, remaining at his post until the hen again returns.

For about the first week the young are fed a soft substance ejected from the craw of the parents into the mouths of the squabs. This substance is simply the food of the parent after undergoing certain changes in the crop, and is known as "pigeon milk."

It is a hard matter to tell the sex of pigeons. Generally the cock bird is larger than the hen, and his continual cooing, activity, and brushing of the tail, are the most direct evidences of sex.

It is interesting to watch the courtship of pigeons. With his head erect, cooing loudly, his wings lowered and his tail spread, he approaches a female endeavoring to strike an acquaintance. If she does not desire to mate she will stand quietly. Should she be approached by one of these gallant fellows, she coos softly and moves her head back and forth, evidently telling him that his companionship is not desired. Should he still persist and get too close she will become furious and strike at him with her bill and one wing. This to him, then, is final warning, and he keeps away.

But in case it should be "love at first sight," she will bow her head, wink her eyes, and show a trembling action of the throat; at the same time her wings will slightly flutter, her shoulders raise, and her tail spread. At times she will reach out her beak as if seeking to be kissed. This coquetry is very pretty.

As a rule the male selects the nest, and endeavors to persuade his mate to join him. Should she not feel ready to go to "housekeeping," he keeps driving and scolding her, every now and then hitting her with his bill. At times he gets very rough, going to the extreme of picking her about the head until the blood comes.—Petaluma Poultry Journal.

FEEDING ALFALFA.

Anwering a query in the Petaluma Poultry Journal, J. H. Davis says:

Authorities differ as to the amount of alfalfa meal to feed as well as the value of the meal as a feed. Some prefer finely cut green alfalfa, and when it can not be produced, cut the dry alfalfa finely and steam it several hours, putting it in a mash with other things as cornmeal, bran, crushed oats and so on. A teaspoonful of the meal to each hen every other day, would, in my opinion, be about right. It makes no difference what time of day it is fed. Some feed it every day. But I am inclined to the belief that the chopped and steamed alfalfa will give better results, as the fowls get some roughness which they need and which is better than too much concentrated feed. As alfalfa is fed in place of grass or green stuff which is largely the feed of fowls when allowed to roam at will, it might be a good plan to rotate the alfalfa feed, giving the cut and steamed feed one day and the meal the next day. And change the times for feeding it. Give it one day in the morning, the next day at noon and the next day at night. Being a purely vegetable feed, and a natural feed, it can not hurt fowls fed in any quantity. It would be a good thing for our correspondent to experiment in feeding it. Experiments are good teachers. When a breeder know a thing himself, it is worth a lot of theories and guesses.

MILLET SEED GOOD FOR BABY CHICKS.

Millet seed or any other fine grain or grass seed is best for the baby chickens. When they are one week old the tender sprouts of the oats are valuable, and make the chickens grow and develop much more rapidly than when given free range or fed largely on more solid food.

It matters not how closely the breeding pen is yarded if supplied with the above conditions and food. The eggs will be composed of the

WHAT OUR CUSTOMERS SAY

Rialto, Cal., June 10, 1908.

Will say that I am a man of thirty years' experience in the poultry business and have used all kinds of Incubators and brooders. I have prompted more than one manufacturer to improve his brooders, as we could hatch the chicks but could not raise them profitably. The "SUCCESS" is the only brooder I have any use for, as we can take the live chicks out of it, and no dead ones. I say Success to you every time, as they save thousands of chicks that would die in other brooders. I took 12 dead chicks out of a brooder the other day that cost more than your brooder and incubator combined. They do the business, that's what counts.
DAN WEBSTER.

El Cajon, Cal., April 12, 1908.

The "Success" Incubators I bought of you, 340 and 612 egg sizes, have both been very satisfactory. I got better hatches from them than any machines I ever used before. They run perfectly, no worry at all. I will want more this fall.
HERBERT OGDEN.

Ivanhoe P. O., Los Angeles, Cal.

The first hatch from the 612-egg Success Incubator was 425 good lively chicks. That's good enough for anyone.
W. E. SMITH.

Inglewood Cal., June 2, 1908.

My 612-egg "Success" Incubator runs more evenly and hatches better and stronger chicks than any of the other makes I have. I will sell off all others and use the "Success", they are the best.
CARL MATSON.

Whittier, Cal., Jan. 12, 1909.

My 612-egg size "Success" Incubator runs with less attention than any other machine I use. Am well pleased with it, says
MRS. W. H. OBEAR.

Calexico, Cal., March 22, 1908.

My first hatch from the 612 "Success" Incubator is just off. I got 416 chicks from 434 good eggs. I never used an incubator before and think that extra good. If I buy more machines you will get the order.
F. PARKS.

Florence, Cal., March 11, 1908.

My first two hatches with the 340-egg size "Success" were above 90 per cent. of the fertile eggs. The machine runs perfectly and I can recommend it to anyone. I hatch eggs from my prize Buff Orpingtons in the machine all the time.
NATHANIEL SMITH.

Fullerton, Cal., January 10, 1909.

I have recommended your machines to all that have called. I have used four of the 612-size in my hatchery, says
L. E. BLACKFORD.

proper material to stand the process of incubation, and the chicks hatched will be fully equal in every respect to those hatched from the fowls given unlimited range.

A MATURE PULLET.

When a pullet has reached maturity, no matter at what season of the year, if she be maintained in good health and vigor and gets the proper kind and quantity of food, she will lay eggs if she has the laying capacity. Let us analyze that sentence a little.

The first point raised is a question of maturity. The pullet must be mature before she lays. If a pullet lays in October she must be hatched early enough in the spring that she will reach maturity in October. A Plymouth Rock hatched the first of April should lay the middle of October or first of November. If they are to lay a month earlier they should be hatched a month earlier. The Leghorns should lay the first of October if hatched the first of April.

STARTING RIGHT.

The thrifty, well cared for chick, kept comfortable and growing, makes a better bird all the way along, costs less money and worry, and is less subject to disease, parasites, etc., than one whose vitality is low for lack of feed or from exposure, says the Dakota Farmer. Good, vigorous stock to start with, and a good, vigorous start, are all of just as much importance as it is to have good, vigorous seed grain, corn or potatoes. Anything that taxes vitality makes more susceptible to disease and poor conditions that may follow later. The chickens hatched out in the stolen nests with natural surroundings and conditions, and sufficiently fed, and then given their own way as much as possible, are the record makers for vigor and early laying.—Commercial Poultry.

White Rocks and White Leghorns

Mr. Walter Hogan pronounced my standard bred "Fishel" White Rocks the best laying type he ever handled. 220 to 250 capacity. My White Leghorns are winning with 220 to 270 capacity. Mated for egg production. My birds have been selected for years for laying. Eggs $2.00 for 15, $5.00 to $10.00 per 100.

H. G. BIDWELL R. D. 2 Sacramento, Cal.

A SIMPLE WATER FOUNTAIN.

Fresh clean water is kept before the chicks constantly, and is kept clean by using a tin can from which the top has been melted with an opening made in the open end three-fourths inch long (high) and one-half inch wide. The can is filled and inverted in a common earthen flower-pot saucer (open end downward), making an automatic fountain which is raised one and one-half inches from the floor of the brooder or coop. If the fountain is used with hens, some way must be provided to keep the hens from knocking the can over. I overcame this by placing a brick on top of the can.—The Standard.

A "Standard-bred" fowl and a "Pure-bred" fowl are not necessarily the same. A bird may not be up to the standard qualifications and yet be a pure-bred. But a standard-bred is bound to be a pure-bred. Utility poultry are fowls bred for increased egg and meat production, and while they are pure in blood may be way off in markings from a poultry show point of view. No fowl can be a successful utility bird unless it is pure-bred.

Harry McIntire, of San Diego, has started on a three months trip to Honolulu. While there he will visit the leading poultrymen and study web and feather as it exists on the Islands. No doubt Mr. McIntire will gain much practical information, and we hope to be able to give a short article to our readers from him.

When the fattening season arrives, according to an experienced goose raiser, keep the fowls shut away from bathing water, and feed barleymeal, cornmeal and beef scraps and some chopped celery. Keep them in a subdued light for three or four weeks, when they can be let out for a couple of days to enjoy the use of a pond. Then return to clean quarters, and feed on barleymeal and milk, and chopped celery, for two or three days, letting them go twenty-four hours before killing.

There are two kinds of fowls, the right kind and the wrong kind. And there are too many of the latter.

Now is the time when it pays to have the birds tame. A house full of wild chickens is inconvenient, to say the least.

Be sure to have the floor high enough to drain well. I have seen hen houses that were lower than the yard and were, of course, always damp.

Incubators

A good chance to get a small machine at a big bargain price. We are overstocked with the small size Improved Pacific, 62 egg capacity. Regular price $10.50, now $7.00 till stock is reduced. Not old, second hand machines, but brand new and first-class in every respect. No better made. Hot water heating; best Sheer Regulators; everything the best. Catalogue free.

Coulson's Special Dry Chick Food

Makes Them Grow

COULSON'S SPECIAL DRY CHICK FOOD, during the five years it has been on the market has justly earned for itself its great reputation as a life-saver for little chicks by its special adaptation to their needs.

THE UTMOST CARE is observed in the selection of each of the dozen or more articles composing this unequalled feed; tender seeds, cracked grains blown free from dust, steel-cut oats, tiny pieces of dried meat and bone, willow and pure bone charcoal, are combined with other very necessary ingredients; every article being selected with special reference to its quality, strength, and desirability for the needs of the young chick.

FOR YOU TO BUY the many different articles composing Coulson's Special Dry Chick Food is quite impracticable; you could not be certain as to their quality for one thing, and the high cost of certain of them when purchased in small lots might lead to their being left out to the detriment of the chick.

TO MAINTAIN the high reputation of COULSON'S SPECIAL DRY CHICK FOOD, nothing is left undone to make it absolutely the best feed that can be made for the little chicks.

COULSON'S SPECIAL DRY CHICK FOOD can be fed exclusively to your little chicks for the first six weeks, at a cost of about four cents (4c) each; and what is of still greater importance, it will do all that can be done in the way of feed to bring them through that critical period of their lives in full health and vigor.

TO RAISE EVERY CHICK you hatch; to have fine, large, healthy chicks; to have chicks that will stand up and crow when eight weeks old; to raise chicks that you will be proud of, FEED COULSON'S SPECIAL DRY CHICK FOOD, THE LIFE SAVER.

POULTRY TALKS.

Do not neglect to furnish green food and meat scraps for the hens at this time of the year if they are expected to lay well. Be careful about feeding stimulants and condiments, as they generally do more harm than good. With good wholesome feed and the premises kept clean and in a sanitary condition fowls will need no medicine. Be sure the biddies have plenty of pure drinking water. Yards that are used continuously for fowls should be plowed often to turn over filth. A good way is to sow them to rye or wheat. The hens will enjoy scratching for the grain, and besides a great deal of it will sprout which will help to supply green food. In the report made by the Kansas State Board of Agriculture, they claim there are at least four things to consider about the question of winter eggs, viz: The birds, the feed, the place of shelter and the peculiarities of the weather. I think the above report is about right. The birds we intend to use for winter layers must be young, early hatched pullets are best. Some breed noted for egg production should be selected and they should be bred for heavy egg production rather than fancy points.

Next, house in buildings suited to the climate where one lives, open fronts are the only satisfactory kind for me. Give plenty of feed, a variety of it including an ample supply of green feed and meat scraps. Feed grain in litter to give exercise. This is the only recipe I know of that will produce a supply of winter eggs.

I am often asked what breed of chickens I consider best? Which is a very hard question to answer and it can only be answered satisfactorily by the individual intending to breed them and what he wishes to produce. If eggs are wanted select a breed of the Leghorn family, if an all-purpose fowl, then select the Plymouth Rock, Wyandotte or Buckeye. If breeding for size get a breed from the Asiatic family and you will be pleased.

Remember the mistakes made last year and try to overcome them the coming year. There is so much written about overfeeding, and so little about underfeeding. I believe there is more underfed than overfed, if a fowl is given the right kind of food and plenty of exercise there is no danger of overfeeding. Don't expect poultry to shift for themselves and return a profit. I don't see why every one don't raise thoroughbreds of some variety, as they are no more trouble than scrubs and are certainly more profitable.—Southern Poultryman.

FATTENING TURKEYS.

The first thing is to stop them from too much running and wandering says a writer in San Jose Mercury. This should be done from their sixth or seventh month on; before that time it is no matter how or what they are fed—they want to run, hunt and wander. This they need for growth and to keep their digestive organs active. Nature has put in them a strong desire for it. When coming to adolesence, their growth in bulk nearing their full measure, having stronger organs for digestion, they are ready to stop their running when invited home to feast, as follows:

Water and Grit.

First, see that they have pure water, sharp grit (charcoal, sea shells, arranged conveniently in long boxes or troughs and kept clean). Then about five weeks before dressing we begin feeding mixed grain of oats, barley, wheat and corn. For the first week we do not give them all they wish. Second week, wheat and corn is fed only; wheat is lessened until on the third week it is entirely withdrawn, and corn alone is fed three times a day. In that way their appetite for corn is cultivated, as at the start they do not like to make a whole meal of it, and if not fed it before may not pick more than a couple of kernels each. Corn must be at least a year old; all grain must be dry and wholesome.

The Last Feeds.

The last ten days they are given all

the corn they can clean up; three times, nothing left to be trampled; sweep it if any. All this time they are left free to pick at grasses or any extra things needed, which they know very well what and where to find; and to play, to fight, to make love and indulge in dust baths. They should not be scared or chased too much; they should be excluded from strange dogs, animals or men. Every day they should be fed on fresh ground, to avoid contamination by their droppings.

Then turkeys get naturally full and smooth; uniformly fat, yet hard and muscular. When dressed, they look a great deal like the corn they ate.

THE VALUE OF MASHES.

Mash feeding has a firm hold on the imagination of poultrymen, and it has some place in practical feeding. But a good many of the arguments for mash feeding for hens will not look you in the face.

Some experiments have been made which indicate that hens cannot make great egg records without a considerable proportion of ground feed. This is for the same reason that it is necessary to supply ground feed to fattening stock to get best results. In each case it is necessary to secure prompt and complete assimilation of the feed consumed.

One of the results of hopper feeding, however, has been to throw some doubts on the imperative necessity for mashes under ordinary conditions, because the dry mash lacks much of the value commonly attributed to the wet mash. Usually, too, the consumption of mash is greatly reduced when fed dry, owing to the unattractiveness of most dry mixtures; and yet the change has not affected egg yield, if properly managed.

I think it is true that the 200-egg hen can hardly be attained on a whole grain ration, but there's only one of that sort in a million, anyway. Most of the rest can reach the full limit of their productive capacity on a slower schedule.

Under ordinary conditions hens will eat and assimilate enough on an almost exclusive whole grain ration to reach any ordinary expectation in commercial flocks.

Aside from this point the chief arguments in favor of mashes are that they cheapen the ration and increase its bulk.

Just how much importance should be attached to the idea that the hen's feed must be made bulky, is not clear to me. So far as I know, no very successful experimenting has been done along this line. It seems that as much is lost by making the mash carry an unnecessary load of indigestible and useless matter as would be lost by ignoring the matter of bulk entirely.—National Stockman and Farmer.

ROUP.

Roup is a contagious catarrh, and will, unless immediately checked, go through the entire flock. Every affected bird should be separated from the rest at once. The swellings on the head should be opened with a sharp instrument and the wound treated with antiseptic such as listerine, or one part carbolic acid to 20 parts water. A 5-per-cent solution of sulphate of copper injected into the nostrils, the cleft of the palate, the eyes, and the wounds made by opening the swellings, is said to be very good.

Sometimes roup takes the form of diphtheria and is more violent than ordinary roup. It is very difficult to cure and if this disease got into my own flock I would kill every affected bird and burn its body. You will save time and probably a part of your flock by killing all the diseased birds and burning them.

Put the rest of the flock in warm, dry quarters, and before putting them in burn a little sulphur in the buildings, first closing all the openings. Do not put the birds into the building for at least five hours after the burning of the sulphur, during which time it should be thoroughly ventilated.

SUCCULENT FEED.

Many a poor chicken has gone the whole summer through, penned up in a yard not much larger than 8x10, without the signs of anything green to eat. It is just as essential for a fowl to have some kind of bulky, green feed, as it is for a cow to have salt. You possibly have observed the eagerness of fowls, if shut up in this manner, should even an apple core be thrown them.

Many a poultryman has made a failure of the business, and the profits gone on the wrong side of the ledger, simply by neglecting to furnish his birds what their system demanded to keep them in a healthy condition. It's the little things that count in the poultry business. Don't let the winter catch you without a liberal supply of cabbage or mangel wurzels; the additional profits from your flock will doubly pay you for the trouble, as well as materially aid in making your fowls contented and happy—Commercial Poultry.

THE MERITS OF COLLIES.

The standard issued by the Collie Club states that in deciding the merits of Collies color is immaterial. This being so, and seeing that classes are made for tri-colors, Blue Merles and sables, also for graduates and veterans, it seems strange that show committees ignore the whites. Assuredly there is no color more attractive for a ladies' pet than white, with sable markings. It is to be hoped that some show committee will try a class for the white Collie, which deserves better treatment than it has hitherto received.

BABY CATALOG FREE

Just Out New Baby Chick Catalog

tells all about the 19 kinds we hatch, and all about our low prices on the thoroughbred hatching eggs and chicks. We ship everywhere, our catalog shows what our customers have to say from everywhere. We hatch thousands of all kinds of chicks, ducks, turkeys, etc., every week. Ollie Peacott, Silverbell, Ariz., says every chick of his shipment arrived safe. T. P. Dickson, Sacramento, 615-24th St., says every chick arrived safe. Our catalog is something new, and worth while to send for.

Pioneer Hatchery Co., 112 E. 8th St., Los Angeles

When the chicks are hatched don't feed them anything for 24 hours, then feed them the best dry Chick Feed you can get. We say that is

West Coast Chick Feed

Read what others say:

SAMUEL R. KELLAM, former president of the L. A. Co. Poultry Association, says: "West Coast Chick Feed is the best feed for young chicks I have ever used. I have given this feed a thorough test, and have always found that it produced fine, large, healthy chicks."

MRS. A. BASLEY, the celebrated poultry authority, says. "I want some more of your West Coast Chick Feed, for it is excellent. It is purer, cleaner and appears better balanced than other feed I had been using, and to tell the truth, I have been experimenting, feeding both together, and they always eat yours in preference."

Ask your neighbors, for there is more of "West Coast" sold in Southern California than all other kinds put together. If not sold by your dealer send us $3.50 and we will send a 100 lb. sack, freight prepaid within 300 miles.

Small Fruits and Vegetables

GARDEN PEAS.

MORE people fail than succeed, in their attempts to grow peas in California. The reasons are many. Very often varieties are chosen which will not do well here. One would think any variety would yield well in California, but if you look into the catalogues of California seedsmen you will notice they do not list one-third as many varieties as Eastern seedsmen, and if you go among the gardeners who grow for market, you will find the list still further reduced—sometimes the list will embrace but two or three varieties. For a number of years the Yorkshire Hero has led all others in popularity, but it is claimed the Pride of Cahuenga will surpass it in yield and is very much sweeter.

Where ground is limited the American Wonder will give excellent returns if you make the soil very rich. And that calls to mind another reason for failure—poverty of soil. It is altogether useless to attempt to grow a profitable crop of peas on poor soil—and nearly all soil in California is poor, from the gardener's standpoint. The gardener in the vicinity of any of the large cities of the Atlantic coast does not think of growing a crop of vegetables without heavily fertilizing the land, using from seventy-five to one hundred tons of stable manure annually, and to begin with his land is about as fertile as ours. With such treatment it takes about 3 years to bring the land up to a satisfactory standard for the production of profitable crops of the leading vegetables. The methods used by Chinamen and Japs would hopelessly bankrupt the eastern gardener in a single season. And if you observe carefully, it only requires four or five years for the Chinaman or Jap to so impoverish our very best soil, that they, even, are obliged to abandon it.

Another reason for failure is unseasonable planting. After you get back from the coast 10 or 15 miles and farther, it becomes a difficult matter to grow peas in the midsummer months. The hot days followed by cool nights make ideal conditions for mildew—perhaps the worst enemy we have in growing this vegetable. From the middle to the latter part of March is about as late as we can plant and expect a good crop, although we often have summers that, up to July, are so cool that it would be safe to plant a month later. Along the coast, however, they may be planted every month in the year with a fair chance for success every time. If I lived in a Coast town and was gardening for profit or for even but the home table, I would plant peas every month, Sometimes the price might be low but most of the time the price would afford a good profit. Avoid attempting to grow peas in frosty locations at such times in the year when frosts are expected. While the plant itself is hardy enough to withstand any frost we are likely to have, the young peas will not endure a hard frost.

Many gardeners back from the Coast plant peas every season in August and September, very much in the spirit of the gambler. If there happens to be a frostless winter they prove very profitable. If destroyed by the frost it is the seed and labor lost.

The dwarf varieties may be planted in rows one foot apart and the stronger growing kinds like Yorkshire Hero in rows two and one-half to three feet apart. Make furrows three to four inches deep and scatter the seeds along the furrow so that there will be a good seed every three or four inches and cover with a hoe or light plow. Many gardeners sow much thicker than this, but if the seed is good, and your soil fertile, this will be close enough.

Peas planted in the spring—say from February 1st and later— should be planted not less than four inches deep but do not cover more than half the full depth until after they are a few inches high when the soil can be drawn into the furrow to the full depth. When the plants are five or six inches high dust sulphur along the row. Some use a bellows, some a gunny sack. Any method that will distribute the sulphur lightly and evenly will answer. Whatever method is used, it will always pay to run the sulphur through a flour sieve to break up the lumps. It will not matter if some of the sulphur falls upon the ground, but it should be in proximity to the row. It is the fumes of the sulphur set free by the heat of the sun that destroys the spores of mildew and it should be used as a preventive, for if the vines once become covered with mildew, no amount of sulphur will dstroy it. Make a second application after the pods have formed.

How to fertilize? Well, if possible, get stable manure and spread it over the ground and plow or spade it in. I should prefer that from the dairy corral, but any kind will do. There seems to be a deep-seated prejudice against using fresh manure. This, I think has arisen because of the injurious effects so often seen in the east, where irrigation is not used. If the weather should be dry the crops often burn up. With irrigation, it is safe to use fresh manure in any reasonable quantity. If impossible to get manure use fine ground bone at the rate of not less than 500 lbs. per acre, sown broadcast over the ground after it is plowed and then harrow or cultivate it in—and do this cultivating or harrowing pretty thoroughly.

It rarely pays to grow the very tall varieties of peas in California because of the difficulty and labor involved in getting brush. In small gardens it will often prove satisfactory. The finest results I ever saw with Yorkshire Hero was in a Pasadena garden where the owner had made a low fence around his garden by driving light stakes about 8 feet apart and stretching telephone wire along and fastening it to the stakes. The stakes were 2½ feet above ground and there were three wires, the bottom one is hardly enough to withstand any soil was sandy loam and after the peas were up to the first wire the soil was mulched a couple of inches deep with manure from the dairy corral. When I saw them the vines were full to the top and loaded all over with such a crop of peas as I have never seen elsewhere.—Q. A. Lobingier.

The Ornamental Garden

BEAUTY OF HOME YARD.

The immediate grounds about the farm dwelling can be made beautiful and sanitary as few other places can. The home grounds should be ample, as large as is consistent with the size of the dwelling, and much larger than most farm home grounds are.

An acre is not too much. Some may think that an acre of land is too much to waste on a simple dooryard, but it must be remembered, that this part of the farm is where the farmer and his family live and spend a greater part of their time, and that the better the home grounds the better will be the life of the family.

It is a wrong estimate of life and property to be forever making money to enlarge the farm in area in buying extra tracts of land for future use, and not improve and make the best of the little spot where the wife and children must spend nearly all of their best life.

Some look forward to and prepare too much for pleasure to come and do not expend any means on making the present the very best that it can be. They let the home grounds and surroundings remain shabby and unimproved, expending the extra money on property to be handed down to the children, or putting it in the bank.

This is wrong when there is any

CLOVER SEED

neglect in home improvement. If the children need help, by all means they need it now while they are helpless more than when they grow up and will be able to fully care for themselves, perhaps much better than we ever shall be able to care for them.

They need the comforts, healthfulness, and beautifying influences of good homes and surroundings in order to make them healthy, strong, beautiful and good. These are infinitely better than inherited real estate, personal property, or money.

The child whose home life is perfect for physical and mental development will go out into the world with a rich heritage. If the home is beautiful and attractive the child when grown older will love to come back to visit the parents who made the home.

The grounds surrounding the farm dwelling should be well drained and graded to suit the location. The main open part of the space should be lawn of good grass and be kept mown low at all times so that air and sunlight may purify the soil.

The lawn is for use, to walk and play on, and should be laid out with that in view. "Keep off the grass" may be all right for city parks, but the home lawn is a green carpeted outdoor floor for every-day use.

Abundance of flowers, shrubs and trees are essentials for completing the picture, but flowers and shrubs must be massed in clumps and borders along the sides, and the trees must be grouped in one place, preferably the rear or somewhat removed from one side of the dwelling.

Under the trees in the cool, shady part of the grounds a children's playhouse or rustic, open structure is a good place for rest and play for both young and old. We can never get too much of the open air, even though we live in the country; and such a covered place under the trees makes a fine nook in which to read or take a nap and fully enjoy the sweets of outdoor life.

Such a play-house is dear to the hearts of children, and they will spend many happy hours each day there; when if no such provision were made they would be in places in which we should not want them.

For wet weather, concrete walks are comfortable and economical. They are cheaply and easily made. They need not necessarily be wide, but there should be enough of them so that all outbuildings and other much frequented places can be reached without walking on the wet ground. Walks a foot wide are much better than none, and such can be made at a trifling cost.

The barn and entire group of farm buildings, together with the grounds they occupy, may be made to harmonize in a general way by proper construction, arrangement, and painting. The grounds about the barn and other feed and stock buildings, which for convenience are located near the dwelling may, and should be, as neat and clean as the home grounds proper. This is both good farm management and a mark of good taste and character on the part of the farmer.

Good fences around all the home grounds and lots are a necessary convenience, and keeping them in good repair adds to the neatness and beauty of the picture as a whole.—Farm World.

PANSY.

These lovely flowers are favorites with all, not only for the brilliancy and variety of their colors, but for the durability of their bloom. Seeds may be sown in open ground in spring or summer, or in hotbeds early in spring. The ground cannot be too rich; coolness and moisture are necessary. Transplant them when an inch high.

NASTURTIUM.

These will always be valuable summer flowering plants. They flower better, however, in a poor, rocky soil, as a rich one has a tendency to make them "run to leaf." The "Tom Thumb" varieties are splendid bedding sorts.

The annual short course for fruit growers is now in session at the State College at Pullman, Washington.

CONSERVATION.

THE National Conservation Commission has recently made public the first of its schedules on which the inventory of the country's natural resources is being conducted. Only a few of the schedules have, as yet, been given out, but between the lines of these it is plainly evident the National Conservation Commission intends to hunt down waste in all its varied forms and to devise some means to prevent it. This is apparent in the general schedules as to each of the four sections of the Commission—waters, forests, lands, and minerals.

For instance, the schedule relating to lands inquires into waste of soil by erosion, which is the washing away of the land. That schedule also suggests waste through "bad agricultural methods." The lands schedule likewise goes into waste in the carrying capacity of the public range in the West. The section of waters is inquiring into how much land capable of irrigation is wasted by not being irrigated. More important still are its suggestive inquiries tending to show that we are wasting our waterways to an alarming extent by not using them as we should. Perhaps the greatest form of waste brought out in the entire schedule is that relating to water power. Two of the official inquiries are as follows:

"Are existing developed water powers put to their full use?"

"To what extent can coal be saved by the substitution of water power?"

Under the head of flood waters, the Commission inquires, "To what extent are flood waters wasted?"

The minerals section of the Commission is seeking to find out "the nature and extent of waste in the mining, extraction and use of mineral products" and "methods of preventing or lessening this waste."

That forest conservation must largely take the form of saving wastes in manufacture seems to be the conviction of the Conservation Commission. The Commission is busy conducting a census by correspondence to find the common wastes in wood-using industries. Queries have been sent to eight hundred manufacturers of cooperage stock for the purpose of getting a line on the waste of wood in the making of barrels and casks.

Similar wastes occur in turning the logs into headings and in the manufacture of barrel hoops. The Forest Service is trying to find just how important such wastes are, with the object of suggesting, if possible, some way of cutting down the drains upon the forests which mean no gain to any one, but loss to all. The returns from the inquiries will form part of the report of the Conservation Commission, when the work of taking the preliminary inventory of our natural resources is completed.

JUST WHAT SHE WANTED.

The lecturer had been describing some of the sights he had seen abroad. "There are some spectacles," he said, "that one never forgets."

"I wish you could tell me where I can get a pair of them," exclaimed an old lady in the audience. "I'm always forgetting mine."—Chicago News.

PROTECTION FOR STRICKEN MESSINA.

Of course, everybody was homeless in the chief city of that beautiful Sicilian isle, after the most appalling calamity of modern times.

Close upon the quick emergency action to relieve actual suffering our government turned its attention to providing comfort and shelter for those bereft of home and habitation. Accordingly an order was immediately placed with the Barber Asphalt Paving Company, Philadephia, by the U. S. Government for over two hundred thousand square feet of Genasco Ready Roofing for the direct shipment to Messina by government vessel from the Brooklyn Navy Yards.

This order was promptly filled by this the largest company in the world manufacturing ready roofing, and the roofing was dispatched to complete homes for the homeless and provide shelter for the shelterless.

The choice of the Government in selecting Genasco Ready Roofing for the purpose is a glowing tribute to the merits of this roofing for the Government is exacting in its requirements and particular in its choice.

An equal amount can not be made with any other tools in the same period of time. Write for "Brown Book" and price list.

THE KELLAR-THOMASON MFG. CO., Covina, Cal.

Queries and Replies

Questions to be answered in this department should be received at this office one week before reply is expected. Write plainly on one side of the paper and sign full name and address. Unsigned communications receive no attention.

Naming Apple.

Please give name of apple which I send under other cover.—H. C., Laton.

The apple is a small, red apple, brightly colored, hard and firm, apparently an exceptionally fine keeper. Round or slightly elongated in shape. It was submitted to Mr. Mathews, one of the largest apple handlers in Los Angeles, and while he would not definitely identify it, thought it was either the Wagener or the Jonathan. Subscribers in sending apples for naming should bear in mind the great difficulty, in fact the absolute impossibility of naming apples in this state without knowing all particulars possible to be known. A mountain grown apple and one grown in interior valleys might have entirely different characteristics though the scions were taken from the same tree. To aid in such identification give fullest particulars as to shape of tree, where grown, and all other possible information. If this apple was grown at Laton it shows remarkable coloring for that section and should prove valuable.

Plowing Under Green Manure.

At what age and size should burr clover and vetches be plowed under to give the greatest amount of fertilizer and humus in the soil? Do they gain most during this respect in the first part of the season or later? What is the best way to put them in the ground so as to get the best results? If they are to be plowed under, to what depth?—M. G. B., Colton.

There is no material difference, pound for pound, in the content of nitrogen between the earlier and later growth. The nitrogen gathering nodules form very early in the life of the plant and we are told it has slightly more value then than when the plant is older, and that there is some loss, especially in humus content, when the plant begins forming woody fibre. But it must be borne in mind that the increase in tonnage is so great after the plant is well rooted that it is desirable to secure the benefit of this as much as possible. Therefore the usual plan is to let it grow as long as possible not to let the soil get too hard from loss of moisture. Probably the best way is to plow under with a plow with a long mold board and heavy chain. Get under six or eight inches if possible without disturbing the roots of the trees. Some orchardists, however, prefer disking, cutting the vines into small bits and working into the upper soil. After plowing under, the next step is to follow with a disk harrow, set very straight, in the same direction in which the plow went first, then following diagonally.

Pearl Guineas.

Replying to the recent inquiry about guinea fowls, Mrs. J. Lenert of Chino writes that she has Pearl Guineas and says: "I think they would stand the climate of Imperial valley, as they originally came from Africa. I have excellent success in raising them here."

Beet Pulp.

Please give me information concerning feeding of beet pulp to cow, as to quantity per feeding, effect on amount and test of milk. Can it be given without other feed?—G. N. S., Riverside.

This question will be answered at length in an article in next week's Cultivator, in the Stock Department. We may say now, however, that beet pulp is an excellent addition to the hay ration, although it cannot be fed exclusively. One experiment station states that the food requirements for 2200 pounds live weight of the stock per day is well balanced as follows: fresh beet pulp 110 lbs., hay 40 lbs., moist beer grains 44 lbs., bruised grains 7 lbs., peanut cake 2 lbs. Some of these feeds are not convenient for California feeding, but it gives the proportion of hay and pulp. It would probably increase the flow of milk, but we think it is conceded that no feed has influence on the test of milk.

Large Potatoes for Seed.

Should large potatoes be selected for planting, or will small size potatoes of good shape do just as well?—S., Soquel.

For years, many growers maintained the small seed were just as valuable for planting and would produce the equal in every way of the larger potatoes provided the smaller ones were perfectly ripe. Under this plan of work it became a settled conviction that seed potatoes would "run out" and have to be renewed from other sections. Now it is generally believed that instead of running out potatoes may be made by proper selection to increase in productiveness, size and quality from year to year. If one wishes merely one crop, it is barely possible that the small potatoes will give very good returns; but the regular planter who values a slight increase in crop and wishes to breed up his seed should choose the most perfectly formed potatoes from the strongest producing vines.

Nitrate of Soda.

When is the best time and what are the best methods of applying nitrate of soda to an orange grove that is now in first class condition?—Reader, Bloomington.

The best time to apply nitrate of soda is after the heaviest storms are over, because it is very soluble and heavy rains after application might cause great loss by leaching away from the roots. As this is a good season to secure its advantages, however, if applied now, apply small quantity now; a few weeks later another application; still later, when the danger of further heavy rains is past give the last application. For instance, if you have planned a 3-pound application to each full-grown tree, give three-fourths of a pound now, and the rest later. If the trees are young, do not, of course, make such heavy applications.

Luglienga Grapes.

A subscriber recently inquired regarding Luglienga grapes. We have a statement from Mr. Roeding that the Fancher Creek Nursery has a very few vines in grafted stock.

Value of Hen Manure.

What ought I to pay for old, dry hen manure per pound?—T. R. M., Ioamosa.

We refer you to the Cultivator for September 10, 1908, in which Mr. Mills answers this question at length. Briefly, we would say, it is worth about $5 per ton.

To Kill Weeds.

Is there any kind of acid solution cheap enough to be practical to kill weeds along sides of flume?—J. B. B., E. Highlands.

Such an application is apt to be disappointing. Plenty of materials, placed on the ground, will destroy growth, but such applications injure practically all plant growth nearby. Within the last few years there have been extensive experiments in spraying with sulphate of iron in grain fields, a solution of 100 lbs. sulphate of iron to each 50 gallons water used. This solution is sprayed over the grain fields and has proved of no particular injury to wheat or other grains while destroying wild mustard,

dandelions, cocklebur, and Canada thistles. We have never heard of its being used on weeds along a flume, but of course in such a case the solution could be made much stronger. We do not know what the effect would be on Bermuda grass and other persistent pests. If you try it let us hear from you.

Live Oak.

Is there any way by which I can hasten the growth of a young oak? Will fertilizer and water help, or is it best to let it alone? It is in very gravelly soil.—R.

To be sure a reasonable amount of water and fertilizer will aid in gravelly soil in establishing a young live oak. It is, however, remarkably discouraging under the best of conditions to watch a young live oak wait several years to establish its roots before it begins to grow perceptibly. The writer prefers the eucalyptus or more rapid growing trees as a rule. Young people may live long enough to see the young tree grow to respectable size, but for all the quicker growing trees have an advantage. The live oak is amongst our most beautiful trees, once it is grown.

Grafting Olives.

I have a large olive tree about ten inches in diameter. Think it is about 18 years old. It is thrifty, strong growing tree, but fruit is worthless being so very small. Can this tree be profitably grafted?—S. H., Nestor.

The olive can be grafted and if the tree is located so as to be valuable for shade and ornament it will probably pay to take up the work of grafting. As a commercial proposition it might be doubtful. So large a tree would have to be grafted very high and in the smaller branches. Use scions not larger than a lead pencil, inserting in April. Graft high enough so the branches will not be over say a couple of inches in diameter. The side graft usually does well with the olive. Grafting is high as this in a large tree will make a great quantity of wood from which the sprouts will have to be continually pruned to prevent the old top reasserting itself.

Agricultural School.

Will you please inform me is there or will there be an agricultural school in Los Angeles in the near future?—W. E. K., Glendora.

There are three high schools in the city of Los Angeles, the L. A. High, Polytechnic and Gardena High, which is in the outskirts of the city though within the city limits. This Gardena high school has as principal a man who is reported to be an enthusiast on the question of agricultural education. His enthusiasm is backed by remarkably good ideas and he is being supported in them by the Los Angeles school board. It is now hoped that the Gardena high school will be the best as it will be the first public agricultural high school in the country.

Billion Dollar Grass.

Will some one who has tried it tell me as to the value of Salzer's Billion Dollar Grass? Does it become a pest like Johnson Grass?—Subscriber.

We know nothing whatever of this grass and ask our subscribers if any have tried it, to be kind enough to report. If it is as big as its name indicates it surely will be equal to Johnson grass.

Bitter Milk.

I have a young cow that dropped her first calf in May 1907, when she was 2½ years old. We were unable to use the milk for a month after the calf came on account of a disagreeable taste. The veterinarian thought it was caused by alfalfa hay, so I changed to oat hay for a time. The milk got all right and caused no further trouble, though I soon changed back to alfalfa. She dropped her second calf in July 1908. This time we had no trouble with the milk until about the first of December, when it began to smell offensive and to taste bitter, (not salty) very much like that of a cow about to be fresh. It would taste and smell slightly when first milked and by the end of 24 hours would be very offensive. Her mother and grandmother were subject to such spells I have recently learned.—Inquirer.

I have a cow about three months fresh and the milk and cream turn bitter in from 30 to 36 hours. Feed alfalfa and rolled barley. All milk utensils are thoroughly scalded both morning and night. Can you tell cause and remedy?—Subscriber.

If you are sure that is a race quality in these cows, they should go to the butcher at once and the strain be stamped out, as it is worthless. First, however, I should give the benefit of the doubt as I went through a like siege in finding out how to make gilt edge butter. I never found a cow giving bad milk. Afterwards I even fed cabbage and onions to see if I could make the cow send the taste into the milk. The taste comes from something absorbed by the milk. I have the cows fed on alfalfa to within an hour of milking time an then put them into a yard until they have breathed off the flavor. The stable is kept clean from droppings and if a cow makes any, a shovel of gypsum is thrown over it to keep down the smells. The stables are kept whitewashed and in sweet condition all the time. I do not say a cow may not give taste to the milk, only I have never had a case of its happening in the dairy here. Try also sweetening all the pails with lime water after they are scalded—thoroughly scalded. Lime water is made by the barrel by dropping into a clean barrel a large lump of lime and working it smooth with a stick in a small amount of water, adding water as it slakes. Then fill up the barrel with water and if there is a small amount of lime in the bottom you know you have a saturated solution by no more dissolving. After twenty-four hours skim off the top and use the clear water of lime to sweeten the milk buckets. A tablespoonful can be added at any time to the milk given to a calf if it has scours.—M. E. S.

Muddy Corral.

How can I best fix my cow lot to keep it from getting muddy? Would concrete be too hard for the cows to be on all the time? Has any one tried oil for this purpose? The lot is 32 by 48 feet.—Subscriber.

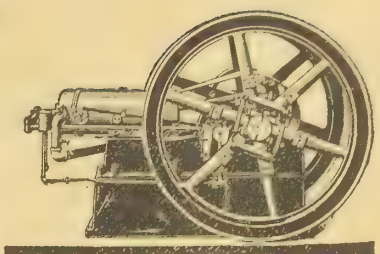
During a season like this, nothing but paving will keep a corral clean. The oiled road is "loblolly" under the cows tramping to the Bermuda pasture. Concrete, well roughened, or else the small cobbles from the washes set into concrete except the top inch would make a perfect pavement for the yard. Cost is the only reason I know for not having this satisfactory pavement in all yards.—M. E. S.

Root Knot.

What is the matter with my logan berries? When planted a year ago the roots seemed healthy. I send a diseased root. Also please tell me how to rid my soil of wire worms.—C. L. F., Colton.

Prof. Smith of the Southern California Laboratory, answers: "The loganberry root is affected by the disease known as "root knot," a trouble very similar to and possibly

A RELIABLE WATER SUPPLY FOR IRRIGATION



AFTER preparing the ground, sowing the seed and getting the crop well started, your greatest concern is for a reliable water supply. You *must* have water to irrigate in season. Your crop may be ruined in a single day for the want of it.

You have a dependable supply of water in the form of low lying lakes, ponds and reservoirs. The problem is to raise this water so you can apply it to the land.

Do you know that you can raise such water and make it available for irrigating all your lands by means of the powerful I.H.C. gasoline engines?

They will not only pump water for you in large quantities, but they do it economically. It costs practically nothing to keep an I. H. C. engine in repairs, and the expense of operating it is a very small item compared to the value of the crops you can raise.

An I. H. C. engine as the basis of your irrigating plant makes you master of the situation. You are independent of the ditch and ditch officers. You have a water supply that is all your own. You can start your engine any time and apply water to your land whenever the crops require it.

Keep an I. H. C. engine supplied with gasoline and it runs dependably, hour after hour, requiring but very little attention. You need return to the engine only occasionally, so you are free to spend practically all your time handling the water in the field.

One of the advantages in purchasing an I. H. C. engine is that the engine can be used for many other purposes besides pumping. It is a general all-round farm engine—an absolutely reliable source of cheap power for operating the grindstone, churn, fanning mill, feed grinder, separator, bone cutter, washing machine, etc. I. H. C. engines are made in many styles and sizes, so that you will be able to find just the engine you want. There are

I. H. C. Vertical Engines—made in 2, 3 and 25-horse-power.
Horizontal (portable and stationary)—in 4, 6, 8, 10, 12, 15 and 20-horse-power.
Gasoline Tractors—in 12, 15 and 20-horse-power.
Famous Air-Cooled Engines—in 1 and 2-horse-power.
Spraying and Sawing Outfits in various styles and sizes.

Call on the International local agent handling I. H. C. engines. He will supply you with catalogs and full particulars. Or, if you prefer, write to nearest branch house.

FREE TRIP TO SEE THIS HAY PRESS AT WORK

LOS ANGELES AND RETURN AT OUR EXPENSE

WE PAY YOU TO INSPECT THESE HAY PRESSES.

Instead of paying a salesman's fare to show you a small model of a hay press, we will pay your fare to Los Angeles and return, not exceeding $15.00, to examine our California Special New Century, full circle, all steel, self feed Hay Press and all others on sale there. It makes no difference which hay press you buy, we pay your railroad fare just the same.

When you see for yourself how this machine has been built expressly for heavy baling on the coast, how strong it is, how easy it is on horses, what smooth bales it turns out, you will understand why we make such an offer. It has 7-in step-over, pull power, high baling chamber, positive plunger rebound; it stands up to its work, no taking off of wheels. Has record of 30 tons per day. We will ship you one to try. If you don't want it we will pay freight both ways. Write now.

ARNOTT & CO., 118 South Los Angeles St., LOS ANGELES, CALIF.

Tanks Tanks

WINDELER'S PLANING MILL AND COOPERAGE

GEO. WINDELER, Prop

Water Tanks, Wine Tanks made from carefully selected stock by careful and experienced workmen. "Tanks that are well made last a long time." It will pay you to get my prices before buying.

Classified Liner Columns

Rates 1½ cents per word per issue. No ad. accepted for less than 25 cents. Our classified columns are the clearing house for the readers of the Cultivator. Here you can insert an ad. for the small sum of 1½ cents per word per issue, and be sure that it will be read by thousands.

FARM LANDS FOR SALE.

GOVERNMENT LAND—LETTER TO inquirers—If you have $160 and want 160 acres good rich soil, fine for poultry, pasture, cows, grain and fruit, near producing oil wells, write me why you do not come to Armona via Goshen Junction, inquire at hotel for my ranch. To get place now—first come, first choice. Bargains. Under improvement plan no more cost for one year, under settlement plan you need not come back for six months, then again six months later. Plenty well water. Convenient to wood for post and fuel. JOE CLARK, Armona, Cal.

FOR SALE—ONE ACRE OR MORE. $300 TO $500 PER ACRE. One-fourth cash, balance long time. In the great and growing southwest. Right in line of rapid development. Water piped to each acre. Land is perfect for the production of potatoes, onions, beans, corn, alfalfa, berries and fruit. Finest place for the home. Surest advance in values. Lowest price ever placed on good land, so close to Los Angeles. Free tickets at our office. INGLEWOOD RANCHO. A2318 330 S. Hill St. Main 6278

FOR SALE—FINE 10 ACRE ORANGE grove near Covina, trees one-third Valencias, balance Navels, full bearing; modern 6-room house and barn; electric lights and city water, near Pacific Electric; price only $16,000. Easy terms. JEROME REYNOLDS, Covina, Cal.

FOR SALE—PALOMITAS VINEYARD 194 acres; 106 planted to choice Emperor, Malaga and Muscat vines, 3 to 5 years old. Part or all. Half cash, balance on easy terms. MRS. M. E. SHERMAN, Fresno, Cal.

ORCHARD HOMES FOR SALE—FIVE acres and upwards; fine citrus and deciduous fruit lands on easy instalments and low interest. Write us today. WYATT & WILSON, Winters, Cal.

FOR SALE—ON EASY TERMS, A highly improved, very productive, well watered and well situated 40 acre ranch. B. F. YOUNG, Huntington Beach, Cal.

I MAKE A SPECIALTY OF ORANGE and alfalfa ranches and exchanges. 826 Main St., Room 9, Riverside, Cal. N. R. BELL.

FOR SALE—7 ACRE CHICKEN ranch with all the stock and tools. Good location. R. DEDLOW, National City, Cal.

BERRY PLANTS.

STRAWBERRY PLANTS FROM ONE year old plants that have not been allowed to bear fruit. Brandywine and Sharpless, $2.50 per 1,000, 35 cents per 100. R. P. NELSON, San Jacinto, Cal.

STRAWBERRY PLANTS—FINE ONES, strong, thrifty, restricted Kellogg method, best varieties, Marshall, Jessie, Climax, and Everbearing, $3.00 per 1,000, $12.50 per 5,000. Address, J. A. POWELL, Ripon, Cal.

WANTED—LADY THOMPSON, TEXAS, and A-1 strawberry plants, also Loganberry. State number and lowest price. None but first class plants wanted. Address, G. H. HOPKINS & SON, Burbank, Cal.

FOR SALE—BERRY PLANTS; LOgans, Giant Himalaya, Mammoth and Lucretia dewberries. Would exchange for rooted Tokay. A. P. HENNING, box 225, Cottonwood, Shasta Co., Cal.

FOR SALE—LOGAN, MAMMOTH, PHEnomenal, Himalaya, Blackberry, Dewberry; strong plants, $10.00 per thousand. Strawberries, $3.00 per thousand. GRIDLEY COLONY NURSERY; Gridley, Cal.

FOR SALE—BERRY PLANTS, BLACKberry, Dewberries $10.00 per thousand. Mammoth Logan, Phenomenal $1.50 per hundred. H. O. SORKNESS, Hemet, Cal.

FOR SALE—LOGAN, MAMMOTH AND Himalaya berry tips, ten dollars ($10) per thousand. F. O. B., Laton, Cal., ADELBERT COOLEY, Laton, Cal.

CLEARING UP PRICES ON ALL kinds of berry plants, pear on quince root, and nursery stock. State your wants. TRIBBLE BROS., Elk Grove, Cal.

FOR SALE—LOGAN BERRY PLANTS well rooted and very strong plants. Write me for terms. Plants ready now. Home 'Phone 2161. Z. A. WOLLAM, Riverside, Cal.

POST CARDS.

LOOK: ONE DOZEN PHOTO POST cards printed from any negative or films for 50c. Your negative returned with order postpaid, all work guaranteed. PHOTO CARD CO., Monrovia, Cal., P. O. Box 214.

MACHINERY.

FOR SALE—COMPLETE LINE OF Union Gasoline Engines for irrigating plants. Some rare bargains in slightly used. Also electric steam and hydraulic machinery of all kinds, new and second-hand. See us before buying. We can save you money. BAILIE & BRANDT CO., Agents, Union Gas Engine Co., 943 North Main St., Los Angeles, Cal.

FOR SALE—RENT OR EXCHANGE, boilers and engines, gas engines, pipe and oil well casing, pumps, all sizes and makes; get our prices before you buy. A. CANNADY & CO., 691 N. Main St., Los Angeles, Cal.

FOR SALE—MEHRING MILKING MAchine with extra parts and covered pail, all in good order. WM. H. BIRD, Box 6, Compton, Cal.

FOR SALE—ONLY USED A VERY short time, good gasoline engine, best make 21 H.P. Cheap. Address P. O. Box 436, Station C, Los Angeles, Cal.

FOR SALE—SMALL MOTOR ALTERnating current, in good condition, cheap for cash. Address K. EUPER, 117 Bruno St., Los Angeles, Cal.

FOR SALE—CHEAP IF TAKEN AT once, small pumping plant complete, in good running order. NW corner Main & Bruno Sts., Los Angeles, Cal.

TREES.

FOR SALE—AT VERY LOW PRICES, large palms of the following varieties, Phoenix, Canariensis, Chamrops excelsis, Chamrops humilis, Cocos australis, Cocos plumosus, Seaforthia, Dracena australis, Dracena indivisa, Musa ensete, Ficus elastica, Italian Cypress, Monterey Pine, Pinus canariensis, Camphors. Must be moved at once at about cost. Satsuma and Bartlett fruit trees, also live and cork oaks, very fine and cheap. Catalogue free, mention Cultivator. H. L. BAUER & SONS, 737 S. Spring St., Los Angeles, Cal.

THE SANTIAGO FROSTLESS NURsery still has some extra fine Eureka lemon trees, choice buds, but they are going fast. There are none better. L. F. THURSTON, Proprietor. Sunset Telephone 354 Orange. Address Santa Ana, R. D. 1.

WALNUT TREES—3 YEAR OLD Seedlings from selected grafted seed of **Placentia Perfection.** Best and cheapest trees in market. G. W. SHERWOOD, Fullerton, Cal.

FOR SALE—LEADING VARIETIES PEACH and apple trees, good stock, bed-rock prices GRIDLEY COLONY NURSERY, Gridley Cal

GRAPE CUTTINGS.

FOR SALE—THOMPSON SEEDLESS and Zinfandel rooted grape vines—first class—$10.00 per thousand. GRIDLEY COLONY NURSERY, Gridley, Cal.

STRONG OUT DOOR GROWN ROOTED cuttings. All kinds of plants. Send for 1, 2, 3c list. GEM NURSERY, Los Gatos, Cal.

FOR SALE—CORNICHON GRAPE vines one year old, $10 per thousand, f. o. b. FRANCIS CUTTLE, Riverside, Cal.

FOR SALE—ROOTED GRAPE VINES, Concord and Agawam, 50c per dozen; $3 per 100. A. E. NELSON, El Monte, Cal.

FERTILIZERS.

NOW IS THE TIME to fertilize for results in the coming crop.

ARMOUR'S "O.T.M.", "B.B.&P.", and "5-8-2" grow big crops and build up the soil. They have been doing it for years.

THE ARMOUR FERTILIZER WORKS, Los Angeles, Cal.

SEED.

FOR SALE—CALIFORNIA BLACK walnut seed in sack lots. Wanted: Mayette, Franquette and Parisienne Walnut scions, also Rupestris St. George, Rip. x Cord. x Rup. 106-8, Rip. x Rup. 3306 and 3309 cuttings, grafting size. Address FANCHER CREEK NURSERIES, Fresno, Cal.

FOR SALE—SEED FROM SELECTED plants, Burbank's Crimson Winter Rhubarb $1 per quarter pound package, postpaid, $3 per pound. A. E. NELSON, El Monte, Cal.

VINES WANTED.

WANTED—A FEW THOUSAND MUScat, Thompson Seedless, and Malaga well rooted vines. IMPERIAL VALLEY NURSERIES, El Centro, Cal.

ARTICHOKES.

FOR SALE—JERUSALEN ARTIchokes, the great winter hog feed. Address, FANCHER CREEK NURSERIES, Fresno, Cal.

POULTRY

BARRED ROCKS, RINGLET STRAIN, direct from the famous E. B. Thompson pens, New York. Have taken more prizes than any other Rocks at The Madison Square Garden Shows. For beauty, size and laying quality, unequaled. Eggs $3 per setting of 15—2 settings, $5. A few cockerels and trios for sale. Agent for the enlarged edition, The Potter System of Selecting the Laying Hen. A. C. CISSELL, 1812 Santa Monica Ave., Hollywood. Colegrove car to Swan Street.

FOR SALE—WHITE WYANDOTTES, Hayes "Bred to Lay" strain. Eggs for setting, $1.50 and $2 per 15, $6 to $8 per hundred. Hens, $1.50 to $3; cocks, $3 to $5; trios, $6 to $10. Discount of 25 per cent. on hens and pullets in lots of 50 or more. Write for particulars. F. E. JUDSON, Carson Heights Ranch, San Pasqual Valley, Escondido, Cal.

BUFF ORPINGTONS—BLOOD AND breeding tells. Five years careful selection for points and laying; results, first prize pullets last year and 50 per cent. egg yield during moulting season this year. Eggs, $1.00, $1.50 and $2.00. Special prices on incubator lots. E. G. WALL, 1920 Monticello Ave., Hollywood, Cal. Phone Hollywood 1943.

HOW TO MEASURE MOISTURE IN your incubator with one thermometer, blue print with table, 50 cents. How to predict night frost with two thermometers, blue print and blank, 60 cents, both for $1.00. CAPT. C. NIELSEN, Sebastopol, Cal.

SILVER CAMPINES, GREAT LAYers, non-sitters, beautiful fowls, splendid foragers. Recently imported from Belgium. Eggs for hatching $3.50 per doz. Write for circulars. E. SMITH, 3610 East First St., Los Angeles, Cal.

LIGHT BRAHMA, FIRST PEN, FIRST Cockerel at 20th Annual L. A. County Poultry Assn. show. Cockerels from same mating $3.00, $4.00 and $5.00 each. H. J. SHOW, R. 1, Santa Barbara, Cal.

WHITE ROCKS—SNOW WHITE, prize winning, bred to lay. Eggs $1.50 and $2.00 per sitting. W. E. B. SMITH, 820 Elm Ave., So. Pasadena, Cal. Phone Sunset, Main 2866.

HUSKINS PRIZE WINNING WHITE Wyandottes—Eggs from Standard matings $2 per 15; $5 per 50; $8 per 100. A. W. HUSKINS, 713 Waterloo St., Los Angeles, Cal.

HOUDAN EGGS, FINEST WINTER laying strain. Setting of 15, $2.00; 30, $3.75. Square deal assured. Order now. MRS. R. HEGI, Box 272, Dixon, Cal.

CHAS. E. SMITH—BREEDER OF Barred Rocks exclusively. Winners of the blue wherever shown. Eggs $3.00 per 15, stock for sale. GARDENA, Cal.

BLACK BEAUTY POULTRY YARDS—Some of the best S. C. Black Minorcas on the Coast. Chicks, $12 per 100; eggs from selected matings, $1.50 per 15, $6 per 100. MRS. A. F. FRESE, box 456, Dixon, Cal.

"CLASSY" WHITE WYANDOTTES—won 3 1sts, cock, hen, pen, besides special cup for best Wyandotte in big Pomona Show. Eggs $2 per 15. P. J. CURRAN, Box 242, Pomona, Cal.

FOR SALE—MATED HOMER PIGEons, good, strong, healthy stock guaranteed. For prices and particulars address CLYDE W. ROHRER, Box 252, Reedley, Cal.

FOR SALE—BUFF ORPINGTONS Steward Strain, eggs for hatching, $2.50 and $5.00 per 13, 100 per cent. fertility guaranteed. ELIZABETH A. WARD, Carpinteria, Cal.

FOR SALE—WHITE MINORCA EGGS for hatching. Day old chicks on order. Selected prize winning stock. MRS. E. BANTA, Calistoga, Cal.

PRIZE - WINNING WHITE MINORCAS. Eggs for setting, $2 for 15; $3 for 30; $6 per hundred, f.o.b. express. C. S. LANE, Santa Barbara, Cal.

FOR SALE—BABY CHICKS, ALL VArieties, 100 lots upwards. J. STANSFIELD, 3301 East 14th St., Fruitvale, Cal.

RHODE ISLAND RED EGGS FOR hatching. Fertility guaranteed. $1.50 per 13; $7.00 per hundred. SCOTT WILSON, Altadena, Cal.

FOR SALE—EGGS FOR HATCHING 75 cents a setting. Black Minorca only. G. W. STERLING, R. F. D. 4, Kern Station, Cal.

O. L. CRANE, BREEDER OF PIT AND Cornish Indian Games. Rural No. 3, Santa Rosa, Cal.

SINGLE COMB RHODE ISLAND REDS —eggs for hatching $2.00 per 15. F. D. CRAWFORD, South Dos Palos, Cal.

VEGETABLES WANTED.

WANTED—TO BUY ALL KINDS OF early vegetables from growers direct. References, Wells Fargo and any bank. MRS. M. VETTER, Santa Maria, Cal.

BULLS.

FOR SALE—ONE REGISTERED JERsey Bull. Dam has given 6,300 pounds of milk with this, her first calf. Price, $50.00. GEO. W. THOMAS, West Central Ave., Riverside, Cal.

identical with the crown gall of many of our fruit trees. There is no known remedy for this trouble, since it affects the roots under ground where no treatment can be applied." Wire worms can be handled only by rotation of crops. That is planting such crops that they are not sustained in the soil.

Frostless Belt.

Please tell me where the frostless belt of California is and how much country it takes in. Does it ever rain where there is no frost? How does garden truck grow in such a place.—Mrs. F. E., Riverdale.

The frostless belt of California is located in various "spots" all over the state. We have, however, never been in any section of the state which was absolutely frostless. Little coves and protected sections are, to all practical purposes, frostless; but a season like the present one has doubtless shown many claimants for such a title that their claim is untenable. There is no thermal "belt," as the thermal lines vary widely up and down the state, according to altitude, possibilities of drainage away of cold air, protection from cold winds, and influence of the ocean. As a rule, all the mesa land within a short distance of the ocean south of San Francisco is almost frostless. Along the Sierra Nevada foothills from even Shasta county south there are other protected spots where the orange is growing and many other semi-tropical fruits flourish wonderfully. Of course in the extreme south, next to the Mexican border, under ocean influences, it is very probable the records would show a perpetual temperature above freezing point. We doubt, however, if any section of the state can show absolute freedom from the white frost. We do not know as to the rainfall in so-called frostless sections, but it would not be materially different from that of other sections under the same influences but not so favorably situated as to temperature. Garden truck does excellently if supplied with sufficient moisture and if the soil conditions are right.

Live Oak Lumber.

What is value of live oak for hard wood floors as compared with other woods usually used for that purpose? Where can I find market for 100,000 feet?—Subscriber.

As it is possible many other subscribers may have land covered with large size live oak trees we answer this in this column. The Southern California Hardwood Manufacturing Company of 1200 E. 8th St., Los Angeles, informs us that it manufactures a great quantity of California grown live oak into flooring. We do not know the comparative value but we are informed that it makes an exceedingly fine floor. The company mentioned has the mill in Los Angeles for sawing up the logs.

Walnuts for Planting.

Where may I secure good walnuts and almonds for planting, or will any good nut bought at the stores or stands answer? Does the outer shell have to be broken? What is the best time to plant and how?—D. B., Hanford.

The best way to secure desirable seed for planting is to get them from the grower and from trees which are

Henshaw Bulkley & Co. E. 3d St. Los Angeles, Cal.

known to produce nuts of the best quality. Even if for grafted or budded stock, then strong growing variety is desired for the stock. The nut, especially the walnut, from the store has been treated with sulphur fumes or bleaching solution which will not improve the germinating qualities even if not entirely injurious. The nuts may be planted as soon as gathered, many preferring to plant them in sand until they sprout, then re-plant to nursery rows. The shell is not cracked in planting.

Dust Spraying.

Can you recommend a system of dust spraying in lieu of wet spraying for orchard trees? I desire to kill moss and insect pests with Sal Bordeaux, arsenate of lead, etc.,—Prunegrower, Morganhill.

The Cultivator will give next week an excellent article on dust spraying by Mr. A. N. Judd of Watsonville. Mr. Judd, who is an ardent believer and worker with the dust spray, gives us his method of preparing the spray. His position is attacked by many others who believe more in the solution spray. Sure it is the dust is much cheaper and for insects perhaps actually as good. For removing moss we do not think it would be so desirable as the water spray.

Almonds.

Will almonds do well in Tulare county? What is the yield per acre and how old will they be before they get into bearing?—J. A. D., Visalia.

This query has been referred to Mr. Mills, and will be answered by an article dealing with almond culture later.

Blight.

What is the matter with my young bearing apple trees? An enlargement of the twigs is shown by the enclosed specimen where the lower part of the twig seems to stop growing, while the upper part grows larger. The fruit on the tree was small and pale and often withered. There were also many dead twigs on last year's trees. What is the disease and can it be controlled by spraying?—Mrs. C. A. M., Orloff.

Prof. Ralph E. Smith answers: The apple twig is not sufficient to show what may have been the trouble with the trees, but by your correspondent's description it would appear that they may be affected with the blight, the same trouble which affects the pear so seriously. This disease cannot be controlled by spraying, but the trees should be gone over very carefully during the winter and all the affected or dead twigs and limbs cut out. In doing this it is necessary to sterilize the instrument, and the best solution for this purpose is 1-1000 corrosive sublimate. This can readily be obtained at the drug store. The blight is not usually as serious on apples as on pears.

SEEDING ALFALFA.

Having derived a lot of information through your farm paper, which I assure you I appreciate, I am going to tell you of my experience in seeding several pieces of alfalfa this winter. Before proceeding with the alfalfa talk I wish to say that I think it the duty of farmers to write of experiments and their results, to be published in the Cultivator, that others may benefit and in that way help build up the modern way of farming. I am a young farmer, having been an electrician, telegraph operator, stenographer, gasoline engine worker, previous to coming on the farm, and of all the trades which I have learned, I like farming the best, and wish to thank the Cultivator for its suggestions which I have benefited by. In reciprocating I will be glad to answer any question for Cultivator subscribers, on electricity, gasoline engine troubles, etc., free of charge.

Now for the alfalfa experience. I first seeded a piece of land to barley early in the fall between my young walnut trees for pasture during the winter. After pasturing four head of stock on this 1½ acre piece of barley, I decided to plow the piece up and seed to alfalfa, but was advised to harrow the barley land and sow the alfalfa in with the barley, which I did before a rain. Now the barley was up about four inches and as thick as hair on a dog, but the seed all took and today is as thrifty as any plant I ever saw; in fact it is much larger and hardier than alfalfa that I sowed on a different piece a week previous. So it is my opinion that the proper way to seed a piece to alfalfa is to sow barley early in the fall and harrow in alfalfa seed during the winter. If I am not misfaken the Easterner sows his timothy and clover on the wheat in the spring and gets a good stand. I believe the secret of this argument lies in the shading of the alfalfa and the damp and moist condition of the barley which feeds the alfalfa plant and keeps it growing. Am I right?—Ernest A. Beard, Anaheim.

In a wet season, yes. But in a dry season you'd better watch out and be prepared for irrigation. Be sure and do not seed so close to the trees but that you can give them clean culture, and then in summer do not allow the trees to suffer for want of water as one is apt to do with inter-culture crops. If that is done the loss to the trees will more than outweigh the feed advantage.

A SWEDE TOPSY.

A little Swede boy presented himself before the schoolma'am, who asked his name.

"Yonny Olsen," he replied.

"How old are you?" asked she.

"Ay not know how old Ay bane."

"Well, when were you born?" continued the teacher, who nearly fainted at the reply:

"Ay not born at all. Ay got stepmutter."—Kansas City Journal.

THE DEADLY PARALLEL.

A dog ran off with a doctor's book
And the doctor raised a shout,
But the dog went on, as the doctors do,
And took its appendix out.
—Henry W. Roby.

THE DOCTOR'S SOLILOQUY.

The dressmaker has some wicked ways,
But calmly I endure them,
She's always giving the ladies fits,
While I sit around and cure them.
—Henry W. Roby.

THE MODEL FARM.

"Does your son know much about farming?"

"I should say he does," answered Farmer Corntossel. "He says he reckons he'll go to town an' make about a million dollars, an 'then cum back an' run this farm proper."—Washington Star.

WHICH MANURE SPREADER.

Which spreader shall you buy? You are agreed that you ought to have a spreader, but which shall it be? Most spreaders are alike in many particulars. But there is this great essential difference between the old line Success Spreader, made at Syracuse, N.Y., which has taken the lead all the way, and other spreaders. The Success Spreader is roller-bearing. Other spreaders are not. The advantage which the Success Spreader thus enjoys is plainly manifest. The less strain, the less breakage. If the operating parts of the machine turn hard, the wheels which drive them, must turn hard. It is the original spreader and it has been over 31 years working them out. It has always been in the lead in adopting approved devices. We known of no point in which the Success Spreader lags behind others in what makes for right operating and proper spreading of manure.

Armour & Co., whose general office address is Union Stock-yards, Chicago, Ill., are sending out a farmers' almanac this year that will be sent to any reader of this paper on receipt of a request for the same and a 2-cent stamp for postage. Being a farm almanac the bulk is reserved for articles of interest to every farmer, such as a scientific treatment on the growing of wheat, a very interesting and comprehensive article on the cultivation of tobacco; the care of live-stock, the making of a fruit crop; the importance of raising a higher grade of meat animals; and some very valuable suggestions on the importance of the use of high grade commercial fertilizer, as well as other valuable articles and hints for farmers in general. It contains a generous sprinkling of art, wit and humor, fashion hints for the women as well as other items of interest and information usually found in an almanac.

Household Department

LITTLE THINGS.

A good-bye kiss is a little thing;
With your hand on the door to go,
But it takes the venom out of the sting
Of a thoughtless word or a cruel fling
That you made an hour ago.

A kiss of greeting is sweet and rare
After the toil of the day;
And it smoothes the furrows plowed by care,
The lines on the forehead you once called fair
In the years that have flown away.

'Tis a little thing to say, "You are kind;
I love you, my dear," each night;
But it sends a thrill thro' the heart, I find—
For Love is tender and Love is blind—
As we climb life's rugged height.

We starve each other for love's caress;
We take, but we do not give;
It seems so easy some soul to bless,
But we dole the love grudgingly, less and less,
Till 'tis bitter and hard to live.

—Andrew Long.

About the House

A HOUSEWIFE of many years' experience writes that "monotony" is the enemy that the woman at the head of a household must fight continually. It is so much easier, for a time, to go on in the same old rut, that before we know it we are tired of everything, and the work that should be a pleasure has become an almost hopeless task. Take for instance the cooking—the same meat, potatoes and bread, served in the same way every day. Just a little variety in the cooking and serving and you will imagine you have something new.

Most farmers' wives know how to make cottage cheese, Dutch cheese or schmierkase,—but do they know that it makes a delicious salad, pretty enough for a "company" salad? Form the cheese into balls about an inch in diameter, and press into the sides the halves of an English walnut or an olive or a thin slice of cucumber pickle. Lay on lettuce leaves or shredded cabbage, or celery cut in dice, and serve with mayonaise dressing.

For those who are so unfortunate as not to like olive oil for salads I will give the formula for a mayonaise that we use, for we do not care for the oil.

Put one half pint of milk in double boiler, cream one third cup of butter and two level tablespoons flour; stir into the boiling milk and stir until it thickens; then let it stand for a few minutes. Beat three eggs until frothy. If eggs are scarce I use only one. Add to them two level tablespoons of sugar, one level tablespoon of salt, two level teaspoons of mustard, and a pinch of cayenne pepper. Mix thoroughly and then add one half cup of vinegar. Stir this into the hot cream sauce and cook until smooth. This dressing will keep for ten days or two weeks.

While talking of salads I want to tell you of an orange salad that I like, and other women like, but which I have never known a man to eat; he refuses it more or less politely. Separate the oranges into sections, or cut them into small pieces, and cover with a dressing of lemon juice, salt and pepper. Heap on lettuce leaves. One day I had no lettuce, so I went out to the grove and got some orange leaves and blossoms and used them instead of lettuce. The salad was an artistic one, with its green and white and gold.

At this season when canned tomatoes are so generally used, new ways of cooking and serving may be welcomed.

For "scalloped" tomatoes, butter a baking pan and fill with alternate layers of tomatoes and bread or cracker crumbs, seasoned with bits of butter, pepper and salt, with well-buttered crumbs for the top layer. Bake until nicely browned on top and serve in the baking dish. For plain stewed tomatoes, season with butter, pepper, and salt, and sugar if you wish, and when hot pour over small pieces of stale bread or broken crackers.

A cream of tomato soup, if properly made, is delicious. To one pint of tomatoes add one quart of boiling water, a slice of onion, a small piece of red pepper, three or four whole cloves, a bay leaf, a small piece of stick cinnamon, one teaspoon of sugar, and one half a teaspoon of salt. Cook for twenty minutes, then strain and keep hot while you heat a pint of milk and slightly thicken it with one tablespoonful of flour and two of butter rubbed together. When the butter and flour are smoothly blended with the milk, add a level teaspoon of soda to the hot tomato liquor and quickly pour in the thickened milk. Let boil up at once and serve immediately with crackers or croutons. A tablespoonful of chopped celery may be added just before serving.

A tomato stew that pleases most people is made by cooking one pint of tomatoes until well done. Season with pepper, salt and a little sugar. Then add a tablespoon of butter, and a tablespoon of flour stirred into a little cream. Let cook a minute or two and pour over bits of buttered bread and serve at once.—Elbepe.

* * *

Preserving Citron.

Will some one "About the House" please tell me if the citron we grow here on trees is the citron of commerce and if so what is the process for preparing it for household uses? —E. S., Fresno.

It is said to be the same. To prepare it for use, the fruit, before assuming a yellow color and also when bright yellow, is picked and placed in vessels filled with brine, and left for at least a month. The brine is renewed several times, and the fruit allowed to remain in it until required for use, often for a period of four or five months. When the citrons are to be candied they are taken from the brine and boiled in fresh water to soften them. They are then cut into halves, the seed and pulp removed, and the fruit is again immersed in cold water, soon becoming of a greenish color. After this, it is placed in earthen jars, covered with hot syrup, and allowed to stand about three weeks. During this time the strength of the syrup is gradually increased. The fruit is then put into kettles with crystallized sugar dissolved in a small quantity of water, and cooked; then allowed to cool, and boiled again until it will take up no more sugar. It is then dried and packed in wooden boxes.

THE SANITARY HOME.

In a real home every member of the family should feel some responsibility, if it is to attain the best moral and physical development. Health is man's birthright, but we often find physical weakness that might have been prevented with proper knowledge.

The walls and floors should be of material that may be easily cleaned. Painted walls may be cleaned without injury. There is a new sanitary wall covering which is particularly good for kitchens and bath-rooms. It is called "Sanitas," and is really an oil-cloth which is made with artistic patterns and coloring. It may be washed like the ordinary oil-cloth. Do not use carpets on the floor. A painted floor with a rug is far better and makes much less work for the housekeeper. In planning a house, be sure that the rooms are arranged so that they may be well ventilated. Have windows that may be raised from the bottom and lowered from the top. There should be a window in every clothes-closet, because clothes should be aired; but very often we find this closet dark, and it is almost impossible to see where anything is placed. There should also be a window in the hall, so that there will be no dark corners to cover up the dust.

In planning a house, many people

pay very little attention to the back stairway. The consequence is that it is almost impossible to carry up a trunk or any large piece of furniture. Plan to have wide stairways with steps that are broad and low.—Mary F. Rausch, Colorado Agricultural College.

WHY NOT?

Once upon a time the house was really a home and all the industries were carried on under its roof. Many a business man returns today with his grandchildren to the old homestead in New England. He shows the children the spinning-wheel, the plain solid furniture, the rag carpets, the huge kitchen, the old trees and shrubs. The house meant the family life and a fine hospitality. Everything was collected and saved here and the house that was built for a young couple was used by their children for many successive generations.

Today the home life is in most cases quite different. The family live here and there and comparatively few people have lived in the same house for twenty-five years. Consequently there is less home feeling. Many young people today start out in a flat or rented house, and make shift to avoid work and responsibility. If they start out humbly, they plan from the first to move as soon as they can "do better," forgetting that they could not possibly do better than slowly and contentedly to build a real home from the foundation.

Women should appreciate the little house and the value of doing their own housework. Most of us are doing our work, so why not enjoy doing it, and make a joy and a sacrament of our home building instead of going at it in a grudging spirit.—C. S. M.

THE WINDOWS.

Window arrangements may make or mar the beauty of a room. They should, therefore, be planned with the utmost care. Not only should the shape, size and location of the windows be taken into consideration, but every detail of the room as well.

The light that comes in through the window is one of the important items. A window having a cold north light or one well shaded by trees may be curtained in light, even bright colors, though pure white muslins are not effective.

A window on the light, sunny side of the house, on the contrary, is more pleasing done in quieter tones, with the net or muslin sash draperies just off white.

The sun shining through a plain white curtain reflects a harsh, glaring light that is most trying to the eyes, besides being inartistic and unbeautiful. The most pleasing light in a room is one that is cheerful and sunny and yet subdued and restful. This very desirable quality of light is gained by the choice of color in the curtains.

In a sunny room a white curtain may be used with good effect, provided it is combined with a figured or flowered chintz or similar material, for this breaks up the all-white glare.

The color scheme is all important. The curtains must harmonize with the room, both in line and color, to be effective. One rule that is invariable in all rooms is that if there is a figured paper on the walls then the hangings should be plain, for if both are figured the effect is confusing.

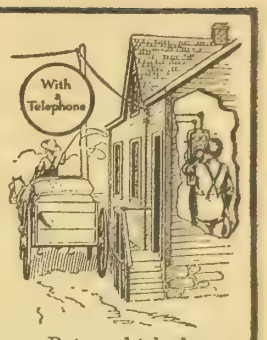
A fancy curtain material, on the other hand, is best with plain walls, for if both are plain the result is flat and uninteresting.

A dainty arrangement for a bedroom window is a shade of flower chintz and a sash curtain of plain white muslin, with an insertion of lace.

APPLE PIE AND MELTED CHEESE

Bake a pie crust in the bottom and on the side of a pie tin; fill with apple quarters stewed till tender and return to the oven, putting a little cinnamon, sugar and bits of butter over. When it is baked enough to set, draw it out and cover with a thick layer of grated cheese. Return to the fire and let the cheese melt and brown. Serve immediately.—Harper's Bazar.

Why Drive to Market Yourself



when you can't afford to leave your work on the farm? With a rural telephone you can talk to town at any time, making it possible for a boy to go and attend to the details leaving your time free for other work.

The telephone also enables you to take advantage of fluctuations in the market and sell your products at best prices. But good telephone service depends first upon the quality of the apparatus installed and without good transmission qualities a telephone system is worthless.

Western Electric Rural Telephones

have highest efficiency and reliability with lowest maintenance cost. Our apparatus has high transmission qualities over long as well as short lines and is used by the leading telephone companies of this country.

We have brought the rural telephone within the reach of every farmer, and with our Free Bulletins before him a boy can install and operate the system. Our telephones are guaranteed.

Cut out this advertisement, write your name and address on the margin and mail it to-day so that the Free Bulletins, which describe the entire plan in detail, may be sent you immediately.

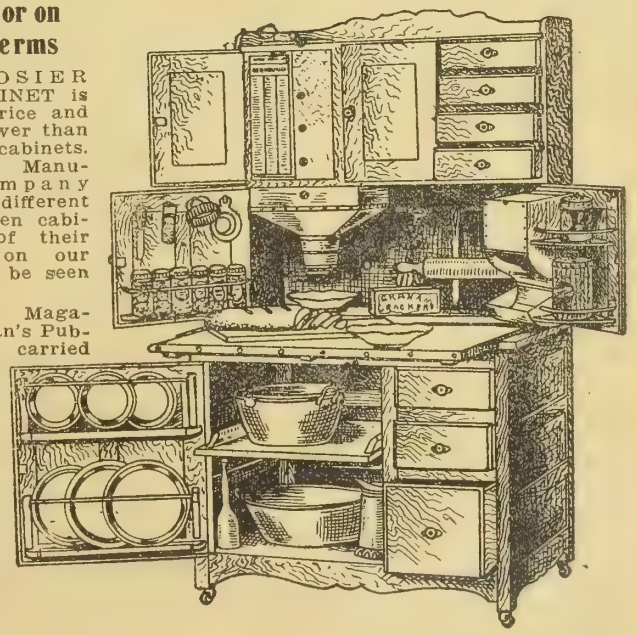
Hoosier Kitchen Cabinets Save Money

Sold for Cash or on Attractive Terms

The HOOSIER KITCHEN CABINET is sold at ONE price and that price is lower than other similar cabinets. The HOOSIER Manufacturing Company makes several different styles of Kitchen cabinets and all of their patterns are on our floors and may be seen at any time.

The National Magazines and Woman's Publications have carried full and double page announcements of the HOOSIER CABINET. These have fully described and emphasized every detail. We are therefore assuming that almost every woman is thoroughly familiar with the HOOSIER CABINET and already fully appreciates its value in the home.



Let us Put one of These in Your Kitchen

HOOSIER CABINETS have a handy place for everything, are provided with flour bin with a sifting attachment, sugar bin, spice cabinet, tea and coffee canister, want lists, aluminum extension tops, plate racks, sliding shelves, breadboards, cupboards, drawers, etc. There is always ample room in this cabinet to accommodate all food supplies and cooking utensils.

A HOOSIER KITCHEN CABINET will effect a saving in materials used and labor expended sufficient to eventually pay its full cost.

The HOOSIER KITCHEN CABINET is appropriate in every home—cottage or palace. We make attractive terms to suit the purchaser.

WHY BOYS LEAVE HOME.

Do we thoroughly appreciate our boys? Of course, it would be hard to find a father who did not have affection for his son, but does the average father, the average father on the farm particularly, do the best he can for his youngsters? No doubt, he thinks he does; but is his method the best? Put yourself in your boy's place. Remember when you were a boy and also remember that times have changed, wages have advanced and that you pay your farm help more than the prevailing rate on your father's farm.

Pay your boy a wage for his services. Better yet, make him your partner in a small way telling him that if he makes good you will increase the interest. Buy him a U. S. Cream Separator and fix his hours of work (when not at school) from say, 7 a.m. to 12. Let him have the afternoon to himself to work for outsiders to earn some extra ready cash.

Charge the cost of the U. S. Separator to his account and show him how to pay for it gradually to you and the interests on the money from the profits he makes in separating the neighbors' milk for them. Then give him a calf to raise all his own, and later some good milch cows. He can use the U. S. Separator to still better purpose then and start butter making on his own account. To run a U. S. Separator will not tax a boy's strength, it is so free from friction and weight. U. S. Separators are so simple that a child can run one.

As a first step toward keeping your boy on the farm, where he will do himself, his parents, the farm and his country the most good, write the Vermont Farm Machine Co., Bellows Falls, Vt., for Catalog No. 20.

Anthrax Cure, Milk Fever Outfits. See O. J. Weber Co., 225-227-229-231 East Sixth street, Los Angeles.

San Francisco Markets

Hay.

Somers & Co. say: The market for choice grades of hay remains about the same although the range of prices seems to be getting more narrow, i. e., the medium and poorer grades of hay advancing indicating a heavy drain on this class of stock which of course is used more extensively when hay is scarce and prices high.

Country shipments although being somewhat hampered by weather conditions are moving very heavily and many inquiries are coming in not only from the smaller towns but the larger cities of the state, showing that they are approaching close to the limit of their source of supplies.

Alfalfa stays up remarkably well considering the grass outlook but from present indications it would seem as though stocks of this hay are not more than enough to supply dairymen and other users of alfalfa who never figure on green feed.

Citrus Market

LOS ANGELES, February 24, 1909.

The campaign of advertising which was carried on all over the Middle West has plainly stimulated the demand for oranges in a way which is most gratifying to those who have made this experiment. As to a increase in prices, there is no great difference though it is probable slightly stronger prices prevail than would have been the case if ths effort had not been made. Oranges have been selling so as to demand in the neighborhood of $1.40 to $1.60 per box f.o.b. California points. The auction markets also as will be seen following have been very satisfactory.

This condition in the face of the fact that much fruit was injured by the extremely cold weather of December which surely had a depressing effect was very gratifying. The injured fruit is all going forward under no name brands so that the established brands are not being injured.

The new trade mark "Sunkist", established by the Exchange is of course put on only the higher grade fruit so that in advertising and urging the purchasing of Sunkist fruits the Exchange insists that its members make good to the extent that the patented trade-

Cream Separators, all sizes, all prices. O. J. Weber Co., 225-227-229-231 East Sixth street, Los Angeles.

mark shall cover only the very finest fruits.

Lemons are selling as well or even better than could be expected with the great number of foreigns that are coming in. While the imported fruit is not in the market very far west of Atlantic sea board points it has an influence on the market conditions to the Rocky Mountains. That is, it is selling at low prices in New York and other Eastern places which has a moral influence on the trade of the West by which they refuse to pay as good prices as the shippers desire. However, returns are not discouraging and fruit is continually going forward.

Shipments.

The total shipments to date since November 1 are: Oranges 6,768 cars; Lemons 1,377, or a total of 8,165 cars.

THE SNOWDRIFT.

When night dropped down, the fields
were dark and dun,
Storm sprites were out—we heard the
north wind blow;
Then when arose the slowly wading
sun
Morning came mantled in a robe of
snow.

White grew the landscape; every
field and knoll
Shone forth transfigured by the
snowstorm's spell;
The trees and fences stood in motley
droll,
Half dark, half whitened by this
miracle.

But where the stone wall held its Parian weight
Of snowdrift, like some Alp or
Apennine,
We saw a sculpture man could not
create,
Smoothed off and chiseled by some
touch divine.

Mute wonder of the myriad molded
snow,
Pure as the stars that sentinel the
sky,
What art could improvise and fashion so,
Unless some godlike power sped
procreant by!

Here plinth and cornice, architrave
and frieze,
Lift up a beauty to the day and sun,
Amidst the silver of the tinseled trees,
That never Phidias or Canova won.
—Joel Benton.

Teacher—Is there any connecting link between the animal and the vegetable kingdom?

Bright Pupil—Yes, mum; there's hash.—Philadelphia Inquirer.

"It costs more to live than it did years ago," said the man who complains.

"Yes," answered the man who enjoys modern conveniences; "but it's worth more."—Washington Star.

"What is this peculiar key on your typewriter? I never saw it on any before."

"Hist!" My own investion. Whenever you can't spell a word, you press this key and it makes a blur."—Boston Transcript.

THE LAND CONTAINS WEALTH.

Beneath the surface the extent of these resources should be determined in every neighborhood. Under any farm or any rugged hill, there may be found great quantities of mineral which should be mined, as people are in need of coal, oil, gas, pure water, etc., and the laboring people need the employment. A group of farmers and prospectors should combine in an effort to have a permanent development organization in every township or school district. By organizing a corporation for this purpose, the burden of loss would not fall on anyone alone and the sure profit in some cases would go to the stockholders in equal measure. Our readers should correspond with the American Well Works, Aurora, Ill., in regard to procuring drilling machinery and ask for catalogue.

ROSENEATH RANCH.

The new poultry ranch of Oswald M. Robertson is built on generous plans. All the houses are lathed and plastered on the outside making them free from draughts. In a number of the houses Mr. Robertson uses the burlap front which we consider good. We have always advocated the open front house with a burlap curtain to let down at night and during damp days. This curtain will absorb the moisture, yet give plenty of fresh air. The ranch is situated at Arlington where the soil conditions are all that could be desired, being of a sandy nature. Mr. Robertson is not new at the poultry business, having had several years' experience, but sold his ranch some time ago and after carefully looking over the country for an ideal location, he selected Arlington, and has laid out his new ranch on practical lines and with the idea of combining the practical features of modern poultry culture.

He breeds White Leghorns and Orpingtons and makes a specialty of selling day-old chicks. Any one desiring stock or eggs will receive generous treatment from the Roseneath Egg Ranch.

DOAK GAS ENGINE CO.

The above reliable San Francisco house is back in the Cultivator again with its regular announcement as to gas engines of all kinds and it will pay our readers to write them for a catalogue and prices.

We take a natural pride in referring to our machinery and pump advertisers as none but reliable firms are admitted to the columns of this paper if we can help it. Both in San Francisco and Los Angeles are found leaders along these lines and pretty nearly every reliable firm in the state is represented. Always mention the Cultivator in writing these firms and make a note of the Doak Gas Engine Co., at 7-9 First St., San Francisco.

LARGER QUARTERS NECESSARY

There has been such a constant increase in my business, and such demand for ABSORBINE, that our present equipment will no longer accommodate us. Consequently we are about to move to 75-77 Temple Street and 273 State Street, where orders will henceforth be received. Prompt attention given to correspondence and all orders filled promptly. I thank you for your past patronage, and solicit a continuance of your orders.

W. F. YOUNG, P.D.F.
244 Monmouth St., Springfield, Mass.

G. A. Murphy of the Sunnyside Stock Farm writes us that he has some fancy boars from New York and a number of fancy young sows of his own breeding, some being from the many times champion sow of P. F. Beauty and others from her daughters and great-granddaughters, which he would like to sell. Mr. Murphy's well-known reputation in California as a stock breeder is a guarantee as to his reliability and intended purchasers should write him for prices.

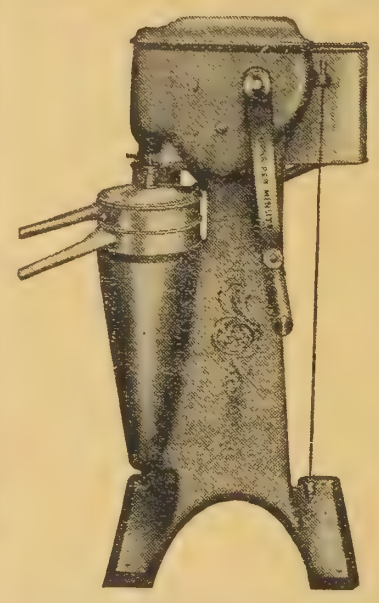
TRADE Sharples MARK 29 Yrs

Here I Am

The plumb bob is one of the handy improvements on the 1909 Sharples Tubular "A" Cream separator. It adds miles to the great lead Tubulars have always had over all other separators.

This "plumb bob" enables you to set the 1909 Tubular "A" perfectly level in a minute—quicker than you could find the spirit level needed to set any other separator. You can always tell, by a glance at the plumb bob, whether Tubular "A" separators are level, thus always keeping the Tubular up to its very best work. Just another example of the "up to the minute" and "away ahead of the rest" character of Tubulars.



1909 TUBULAR "A"

Common "disc" or "bucket bowl" separators require more careful leveling than Tubulars. Yet, to level these common separators, you must place a spirit level on their frames. If their frames are a little out of true, as they usually are, the leveling of the common "disc" or "bucket bowl" separator is largely guesswork.

It is the easiest thing in the world to level the Tubular "A" cream separator shown here. Simply wedge up under the corners of machine until the point of the plumb bob hangs directly over the point of the plumb bob center, or plug, set into the base of the frame. Done in a minute and always right. Observe the low supply can on the Tubular—you need not move it to take out the bowl.

Tubulars Are Different From All Other Separators

Tubulars are built on absolutely correct principles—that is, Tubulars have a bottom fed bowl hanging below a simple, frictionless ball bearing. The one piece frame and the permanent, compact, strong construction of Tubulars enables us to add to Tubulars some very handy devices which it is impossible for other manufacturers to use on their constantly changing common "bucket bowl" machines.

The incorrect principles of common "bucket bowl" machines—that is, a top fed bowl set up on top of a spindle—make all such machines unsatisfactory and necessitate constant changes that are merely makeshifts and not improvements.

Tubulars are built in the world's greatest, best equipped cream separator works. We have additional Tubular factories in Canada and Germany. Tubular sales for 1908 were way ahead of 1907—way out of sight of any competitor, if not all competitors combined.

Our 1909 Tubular "A" is better than any previous Tubular and is guaranteed forever in every part.

The Mealy Bug on Citrus Fruits

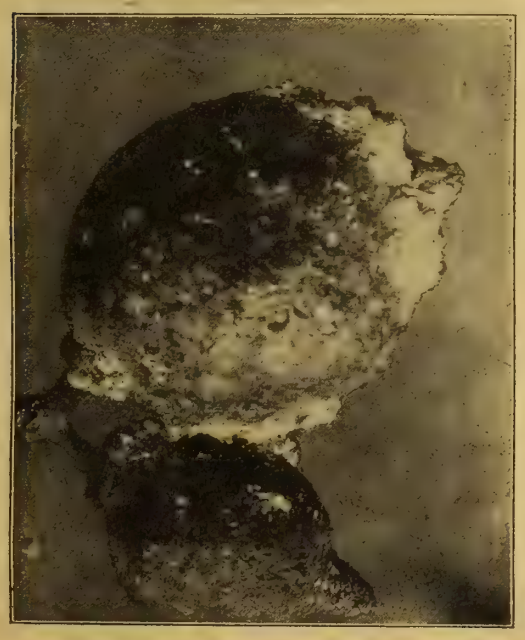
From the Report of the Claremont Farmers' Club

Articles by Commissioner Smith of Ventura County and R. C. Allen of Bonita

We gave last week, a short extract from the Claremont Farmers' Club Report, and now give a continuation in the report made at that meeting by Commissioner Smith of Ventura County, also R. C. Allen of Bonita. We also give from the engravings furnished by the club, illustrations showing the infestation from mealy bug. The Claremont Club is worthy of commendation for this work, which is not taken up without considerable expense to its members, but the results are freely given for the benefit of other horticulturists not connected with its own organization.

I WILL first give something of the damage done by the mealy bug, and its dangers. From close observations in a badly infected district I would say that the mealy bug is by far the most damaging and dangerous pest now in the Southland. I believe that the citrus industry is threatened by the invasion of this insect as it has not been threatened since the ravages of the Icerya purchasi, before it was checked by its natural enemy, the Novius (Vedalia) cardinalis. In prolificness, in endurance of hardships, in power to spread, and to do damage, no pest in the South is nearly its equal.

The pest attacks equally effectively the orange and lemon. It is commonly supposed, I believe,



The Citrus Mealy Bug on Lemons.
(Photos by Commissioner Smith.)

that the navel orange is the principal sufferer. This is not the case. An equal if not a greater damage is done the lemon because of the additional time taken in the packing and curing of the fruit and consequently greater rotting.

The mealy bug atacks the stem, leaf and fruit. In a badly infected grove as high as a hundred of the pest can be found upon a single leaf. I have counted as high as four hundred of the pest upon a green orange not an inch in diameter. As with all Coccids, the mealy bug is continually sucking the sap from the tree. It forms a honeydew, as do most of the other scales, only in far greater quantities, thus causing a dense smut and consequently smothering the leaves. The pest hunts the protected places. Consequently it is found around the stem of the young fruit. A large amount of dropping of the newly set fruit is thus caused. The fruit is wounded and injured, thus causing a great deal of rot. The smut upon the fruit is difficult to remove by washing, and more rotting is caused by the severe treatment necessary to remove this smut.

The pest is exceedingly prolific. A mature insect lays from 350 to 400 eggs. These hatch in 9 to 10 days, so its enormous power of reproduction is seen. An additional danger is caused by the fact that any disturbed insect immediately goes to laying eggs. The insect need not be more than half grown for it to begin to reproduce itself. This makes treatment by direct means, that is, by spraying or fumigation, inadvisable, unless the most thorough work is done. We experimented with a water-white oil spray of 8, 10, 12, 15 and 20 per cent strengths. No damage to the tree was done by any of the sprays. The 8 and 10 per cent were not very effective. The 12 per cent seemed about as effective as the higher percentages. A 3 per cent distillate spray was also tried, but was not effective, not so much as the 12 per cent water-white oil spray. The 12 per cent spray seemed to be very effective at first and for a time it looked as if we could control the pest in this way. But the insects that were left, being disturbed, immediately went to laying eggs and in a short time the tree would be in as bad or worse condition than it was before treatment. This was partially due to the fact that the parasites and predaceous insects were also killed. The insect protects itself very thoroughly, as does the white scale. Thus the spray had to hit it direct, under high pressure, or it was of no avail. This cottony secretion also protects it from the hydrocyanic gas, especially are the eggs protected.

The pest is always capable of movement and, until it begins to lay eggs, is often moving from place to place. The power of movement, combined with its power to live a considerable time without food, makes it many times more easily spread from one place to another than is the purple or red scale. I have put specimens in a vial and closed it with cotton. In a month's time instead of the few specimens that I had put in the vial there would be hundreds of the young insects waiting to commence feeding.

We have done considerable work in experimental fumigation and I will give the dosage and results. In all cases the measuring system of Mr. Woglum was used and care was taken to be exact in the dosage. You are familiar with Mr. Woglum's purple scale table and know that the dosage per 100 cubic volume varies according to the size of the tree. Thus a large tree, say 40 feet over by 50 feet around, would not require so much cyanide per 100 cubic feet volume as would a smaller tree, say 20 feet over by 30 feet around. This is because of the decreasing area of tent surface per 100 cubic feet of volume as the tree becomes larger. Consequently there is a smaller evaporation surface per 100 cubic feet of volume. All trees which we experimented upon were large, nearly filling a 45-foot sheet, so that for a small tree the dosage given here would have to be increased to get the same results that we got.

We used a dosage of 1 oz., 1¼ oz., and 1½ oz., and 1¾ oz., per 100 cubic feet. On the 1 oz. trees a great many live mealy bugs were left. The 1¼ oz. gave a little better results, but a great many of the pest were left. A very little burning was done with this dosage. The 1½ oz. gave quite a bit better results, but too many of the pest were left to make the treatment effective. A little of the very small fruit was burnt, but the burning was slight and practically no damage was done. The 1¾ oz. per 100 cubic feet gave good results; on examination a week after the dosing no mealy bugs being found. The burning was not bad, although some quite large fruit was burnt. For the size trees that we did, this dosage figures out about 100 per cent heavier than Mr. Woglum's purple scale dose. With this dosage most of those upon the ground were killed, although the eggs were not all destroyed.

Where the pest is piled up several deep those on the outside are much more easily killed than are those beneath. This is for two reasons. Those beneath are somewhat protected. Those beneath are sucking the juices of the tree and so have a much greater power to resist the gas. Although apparently dead the next morning I found that they would revive later. In all cases I found that those feeding were much more difficult to kill than those that were crawling. For this reason many of those on the ground would be killed although the gas was much less dense than it was higher up in the tree.

The difficulty of treating by direct means is increased by the large number of host plants that the mealy bug feeds upon. They are found on different species of palms, many weeds, on pumpkins, etc. I will give a few suggestions for treatment. I believe that fumigation, using a dosage of 1¾ oz. per 100 cubic feet will control

The Long-Tailed Mealy Bug, Which is Also Found on Citrus Trees But is Never a Serious Pest.
(Photo by Mr. Essig.)

the pest and prevent its spread, if the situation is taken in time. This dosage will burn the trees some, but a lighter dosage endangers the success of the work. Repeated inspections should be made of the infected and surrounding orchards. All weeds should be kept from the orchard. Also it will help materially if all the old fruit and as many of the leaves are burned as pos-

With the Citrus Growers

PROPAGATION OF THE AVOCADO.

UNTIL very recently the progagation of avocado trees as a commerical enterprise was not undertaken, and the only method employed to extend the culture was to plant the seed where the tree was expected to fruit. Under this method no extensive plantings were made, since the resulting crop proved too variable and uncertain. All species of plants grown from seed are subject to variation. Our principal fruit trees, without exception, must be propagated by a sexual means to obtain even an approximately uniform product. It has been asserted frequently that the avocado comes true to seed, and until the growing of it was taken up for commercial purposes this view was generally accepted. In fact, only a few years ago it was generally believed that avocados could not be budded and it has been but recently demonstrated that budding and grafting are practicable.

Mr. Henry Davis, speaking before the Farmers' Institute of Hawaii, February 4, 1905, said. "I can positively state that I have planted seed from selected fruit, both as to size and quality, and the resulting tree upon bearing produced fruit entirely different from the original." The experience in Florida with seedling avocados is quite the same as in the Hawaiian Islands.

The budded orchard has so many advantages over one consisting of seedlings that it is not at all probable that any grower would plant seeds in order to establish an orchard. A few good varieties can now be obtained in limited quantity from nurserymen. The present high prices indicate a strong demand for the stock rather than a difficulty in the operation of budding. There are now thousands of seedlings that are producing fruit; among these will be found a few of such superior excellence that buds ought to be taken from them for propagation.

Budding.

The simplest form, known as shield budding, is the best one to employ for the avocado. This not only proves very successful, but admits of being done most rapidly. The operation is very simple and the same as that employed in budding orange trees in California.

When the buds have taken, the wrapping should be removed, and a week or two weeks later the stock should be lopped. Here is where considerable difficulty wll be experienced, as a vigorous growing avocado stem will snap off rather than be lopped. If the entire top is taken off it is apt to prove fatal to the bud. Where the stock happens to be very brittle it becomes necessary to resort to ringing; this should be done two inches or more above the bud. Where ringing has to be practiced it should be followed by cutting back the growing tips of the stock so as to force the bud along, and any buds of the stock that have been forced into growth as a result of the ringing should be removed.

As soon as the buds have grown to the desired size and the wood has matured, the trees must be taken from the nursery and set out in the places they are to occupy in the orchard. In transplanting a considerable portion of the top should be cut off; otherwise the amount of evaporation from the leaves will be too great for the plant and the death of the tree will result. The extent to which the top must be cut back will depend upon the proportion of the roots that has been lost in the digging. When the trees have been set out some kind of shade should be provided to protect them from the direct rays of the sun.

MEALY BUG.

(Continued from Page 243.)

sible. No fruit from an infected orchard should be taken to the packing house.

Those inspecting should be exceedingly careful not to carry the pest from an infected tree to a clean tree, as it is exceedingly easy to get it upon the clothing and carry it.

I believe that experience has proved that the final control of this pest will come through parasitic and predaceous insects. This has been found to be the case in San Diego and in some of the Northern points. Nearly all the Coccinellids attack the pest. The Rhizobius ventralis and R. lophanthae have increased greatly in this district and are doing much to check the ravages of the pest. The Chrysopa and Hemerobid flies also help materially. However, the predaceous insect that has controlled the pest in San Diego is the Cryptolaemus montrouzieri, a ladybird. It has done wonderful work there and should be introduced after fumigation. They can be secured of Mr. Austin, San Diego, upon payment for his services. An internal parasite, a Chalcid fly, has done good work in some Northern districts.

Delay is fatal in handling the pest. For this reason this district is so badly infected. We are trusting entirely to parasitic and predaceous insects, except in new infections, where we follow the method that I have outlined.

I would make one other suggestion. That is, that the use of tree tanglefoot after fumigation might give good results. It would keep any live insects on the ground from going into the tree. I have not tried this and do not know how effective it would be.

What I have written and the method of treatment that I have outlined applies to this district. Conditions may be different with you. Examination will show this.

I hope that what I have written may be somewhat of value to you and that you will be successful in checking the ravages of this most destructive pest.—P. E. Smith, Horticultural Commissioner, Ventura County.

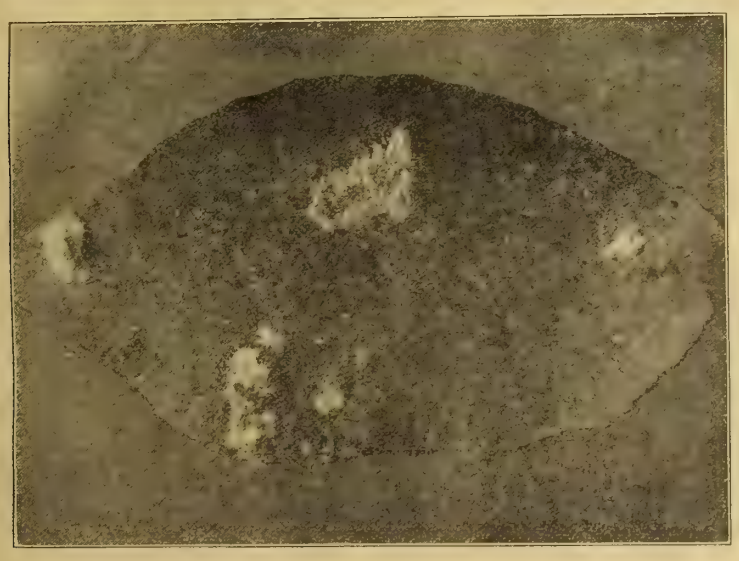
Mr. R. C. Allen of Bonita, San Diego county makes the following report:

The first I ever heard of this pest was some ten or a dozen years ago, when it appeared in Mr. Granger's orchards in Paradise Valley, probably not more than three miles in a straight line from our orchards. When the drouth came on, his orchards were abandoned and we heard no more about the mealy bug. At that time its operations seemed to be confined to a very small area, not more than a half a mile wide in every direction. Three years ago last September, the mealy bug appeared in our orchards in three separate localities.

Larvae of Cryptolaemus Eating the Citrus Mealy Bug.

The first time that we had the bug it did not spread much. We introduced the parasite—the Cryptolaemus—together with it. I do not think that the parasite did much work, for the reason that we immediately began to attack the bug ourselves by distillate spray and by fumigation. When cold weather came on in December, as usual. That fall we had fumigated our entire orchard, but this had no effect whatever upon the mealy bug.

In consequence of its remaining on the trees throughout the winter, the Cryptolaemus increased very considerably, so that last summer it was present in immense numbers. When fumigating last fall, I set aside three



Egg Masses and Young Citrus Mealy Bugs on Lemon Leaf.

the mealy bug disappeared and we saw no more of it until the following August. That year we introduced more parasites, which we got in San Diego, and also again tried to exterminate it with the distillate spray. Our efforts in this direction amounted to nothing. The winter of a year ago, as you know, was very warm, and the mealy bug did not disappear patches of about an acre each in different parts of the orchard where the mealy bug was bad and the Cryptolaemus most abundant. I did this for the purpose of preserving and multiplying the latter. In this we were very successful, and after the orchards had been fumigated the Cryptolaemus seemed to spread pret-

By J. W. Mills

DUST SPRAY.

MANY inquiries regarding my experiences with dust spray lead me to ask you to publish the following as it will answer many of your readers who write to me regarding the subject.

First, I use fine hydrated lime as a conveyer (in place of water) for any or all insecticides or fungicides. The dry lime does not set up any adverse chemical action, hence either one or all known remedial agents can be used at one and the same time. For instance, take this formula: 40 pounds of the lime, (being air slaked it is dead as far as forming any cement or hard scale is concerned when it gets wet), and two pounds of Paris green or codling moth, horn caterpillar (tussock moth), green, black or apple aphids, tent caterpillar, or any leaf or fruit eating insects; and for fungi such as apple scab, shot hole, blight, powdery mildew, and moss, add two pounds each of Sal-Bordeaux and double sublimed sulphur. Even if I have no fungi I put one pound of Sal-Bordeaux with the Paris green, as it is an insecticide as well as a fungicide.

These can all be put on at one spraying and at the proper time, which is when the trees are one-half out in full bloom. The reason for selecting this time is that the fungi spores are very active and destructive to pollen and the blossom stems at their base when in clusters, causing them to drop as well as the fruit later. My success in continuous good crops and clean fruit every year I attribute to this method and time.

At that time, too, the terminal buds are breaking out with their tender leaves, a fit subject for fungi, causing that distressing disease, the powdery mildew. Again, the leaf and fruit eating insects are just hatching, the age when easy to kill. Two weeks later it would take double or triple the amount of Paris green to kill the hardest of them all, the horn caterpillar, so there is economy to be considered as well.

Two men, one horse, and a power blower screwed to a low orchard truck will spray well 20 acres a day of full bearing trees.

At the time to spray, the ground is often too wet to use the heavy, cumbersome, and expensive water spraying outfit. Besides the dust finds every minute spot and is always ready for the enemy, while the little hairs or fuzz on the very young fruit or leaves prevents the water from wetting at the bottom of them, hence the enemy is safe.

I want to say that neither rain nor wind will mash or blow off the dust. It can be put on at any time, but the dryer the better. [We assume Mr. Judd means less freedom from rains. In the interior, warmer valleys, a foggy morning when dew is on is most satisfactory for dry spray. Watsonville leaves are nearly always moist enough to take the dust.—Ed.] Wind makes no difference, except the inconvenience. If the trees are set on the square I drive diagonally so the team need not stop, as then the trees are not opposite, and the operator will have time to change the pipe over to the tree on the other side.

For mixing, I take a whisky barrel. I saw a square hole as large as the space between the middle hoops will allow. On the edge of the hole I tack a piece of canvas twice the width of the distance around it, equalizing the fullness. Sew up the seam. This cloth will form a funnel shaped tube. To mount the barrel so as to turn, I screw one inch gas pipe to a flange on the ends of the barrel, long enough to reach outside a 3½ foot box plus the frame, which is in the form of an A whose legs reach to the bottom of the outside of the box and far enough above to permit the barrel revolving in the notches made in the top of the A's (to admit the one inch pipe) to clear the top of the box so as to prevent the surplus canvas that is half a yard long from dragging on the edges of the box while turning back and forth a few times. Do not fill the barrel too full and when all ingredients are in, tie the canvas and turn the barrel until the ingredients are thoroughly mixed.

Untie the string and the surplus canvas makes the spout to lead the stuff when mixed into the box as well as having served to put it in the barrel. Four pieces of pipe, 16 inches long, and four elbows, will make the extensions and handles to turn with. Nail a cleat around the box to keep it on the truck. Put on a good cover and line the box with cloth put on with good strong paste, thus saving much dust that will otherwise find an outlet.

I never have found it necessary to spray but once. Perhaps in a different and a dryer climate where the codling moth is worse than here a spraying six weeks before harvest would be of value, leaving out the sulphur and one-half of the Sal Bordeaux. Experience will dictate in every place.—A. N. Judd, Watsonville.

• • •

Mr. Geo. W. Pierce of Davis was asked to give his experience on dust spray, but he writes as follows:

Yours relative to the "Dust Spray" is at hand. In reply will state that I have not used the dust spray on my orchards but expect to do so on my almond orchards this season. Some of my neighbors have used this spray on almond trees and recommend it highly. It seems to have been effective in some conspicuous cases. With this as a basis, together with cheapness and ease of application this manner of spraying is likely to be fully tested and its efficiency definitely settled.

In this region of dry air and freedom from fogs the application must be made in the early morning or on days of relatively high humidity.—Geo. W. Pierce, Davis.

FACTS ABOUT GRAPES.

How long the grape has been in cultivation by man can never be fathomed. Profane history does not reach back to the first plants of the first wine made from the grape. It is interesting to note that grape seeds have been found with the remains of Swiss and Italian lake dwellers, in European graves of the Bronze age, and in the tombs of the Egyptian mummies. The vine is frequently the subject of metaphor in the Scriptures

—to dwell under the vine and fig tree is emblematic of happiness and peace.

Perhaps no plant and its products are used in so many ways and for so many purposes as the grapevine and its fruit. We enjoy the grape in the fresh state, or, when dried, in the form of raisins; the unfermented juice and wine are important items in the household economy and medicine, while the grape yields many other products and by-products. The vine itself gives pleasure to the senses by its fragrant blossom, beautiful foliage and luscious fruit; it affords shade and shelter; various parts of it are employed for divers purposes; and the wood is used for fuel in the manufacture of furniture and other useful articles. In Switzerland the leaves are applied to medicinal or surgical uses. For cuts and fresh wounds they are esteemed a sovereign remedy. Decoctions of the juice of the leaves are used in poultices. An agreeable tea is also made from the leaves, which is said to greatly strengthen nerves. In its use more sugar is necessary than for tea from the tea plant. The leaves are also excellent food for cows, sheep and hogs. The "tears" of the vines used medicinally, are a limpid exudation of the sap at the time the plant begins budding. The liquid is collected by cutting off the ends of the canes, bending them down and sticking the ends in the neck of a bottle, which will be filled in a few days. The wood and branches are used in the manufacture of baskets, furniture, rustic work bark for typing materials, etc., and when burned furnish potash and salts. The wood of the grape is said to be of the most lasting nature, very beautiful in its texture. The columns of Juno's temple at Metapont, and also the statue of Jupiter at the city of Appolonium where made from the wood of the vine. The great doors of the cathedral at Ravenna are made of vine planks, some of which are twelve feet long and fifteen inches broad.

It is difficult to accurately estimate the age of vines by the usual methods of counting the rings, because the yearly growth is not distinctly marked. Some authors state that the vine equals and even surpasses the oak in point of age. Pliny mentions a vine 600 years old. It is stated that some of the vineyards of Italy held good 300 years and that vines 100 years old are accounted young. The celebrated vine in the conservatory at Hampton Court England, planted in 1769, had in 1830 a stem of thirteen inches in girth, and a principal branch 114 feet in length, the whole vine occupying more than 160 square yards; and in one year it produced 2,200 bunches of fruit, weighing on an average of a pound.

A wild grapevine upon the shores of Mobile bay, about one mile north of Daphne, Ala., is commonly known as the "General Jackson vine," from the fact that Gen. Andrew Jackson twice pitched his tent under it during the campaign against the Seminole Indians. In 1897 the trunk of this vine was reported to have a circumference of 6 feet 1 inch at its base.

A vine now standing in California planted in 1842 by a Spanish woman, covers nearly an acre, and it is estimated that 800 persons could find protection from the sun's heat under its branches. The first election in Santa Barbara county under American rule was held beneath it. In 1893 it bore eight tons of grapes and in 1895 over ten tons. The trunk of the vine is 7 feet 8 inches in circumference.

What is considered the largest vine in the world is a scuppernong grapevine on Roanoke Island, North Carolina. According to tradition of the island, this vine was planted by a member of the first Anglo-Saxon colony in the United States in 1586-87. It is still hearty and vigorous, covering over an acre of ground and yielding today a large crop of fine, large grapes. The parent stem is larger than a man's body.—Guy E. Mitchell.

GREAT PRODUCTION OF TABLE GRAPES.

At the State Fruit Growers Convention Judge C. W. Norton of Stockton spoke as follows on the necessity of organization to profitably dispose of the table grape output:

"Within the next ten years it is safe to say that the output of Tokays, without any more planting, will be quadrupled and that within that time, instead of being called upon to market 4000 carloads, we shall have 16,000 carloads to find a market for.

"These figures are truly startling. Not so much on account of the growth that has been made in the last thirteen years, but the prospects in the next ten. Certainly not an encouraging outlook for prospective planters. Indeed, the man who would plant Tokays in the face of this showing would, to use a popular expression, have to have his nerve with him.

Marketing the Fruit.

"How are we to handle and successfully market this vast quantity of perishable fruit? The answer is, by improving the methods of marketing the fruit. First reduce the quantity to be shipped by eliminating everything from eastern shipments except strictly first-class grapes. We must educate our growers to raise the highest possible percentage of choice stuff and they will find that one-half of their product, properly culled and packed, will bring more money than all if it were put up in any old way. Let them bear in mind that there is more profit in one crate at $2 than there is in eight crates at $1.

"Again, we must widen the markets and reach more people with our fruits, and we must extend the period of marketing by improved methods of packing. Along the lines of reducing the output by relentless culling too much can hardly be said. I have said that we must educate our people along this line, and so we must; but it is probable that experience is doing more to teach this important point than any amount of friendly counsel can do.

"As to the matter of widening our markets so that we may reach more people and get better prices, nothing can be done without the co-operation of shippers and growers for the improvement of the quality of the pack to be put up, to the end that we may make our fruit so excellent that instead of its being a drug on the market, it may be eagerly sought after in all quarters of the country."

Almost the entire sugar industry of the Hawaiian islands has been developed since the annexation of those islands in 1898.

One peach planter is engaged in putting out 300 acres of peaches near Atwater, Stanislaus county.

Small Fruits and Vegetables

THIS MONTH.

GROUND is in a fine condition for spading. Rake off and burn leaves and vines or rubbish. Egg plant, peppers, squash, cucumbers and other tender plants that have been started in a hot-bed the month before may be set out in the open in March. Another sowing of the same vegetables can be made for a succession of crops. Squash, sweet corn and beans are planted in the average locations usually free from frost. In fact, all kinds of vegetables may be set out from now on. Keep a supply of tobacco dust, sulphur, and insect soap on hand to fight the insects that always appear on melons, cucumbers and squash when they have two or three leaves. Stake up the berry bushes and spray them if infested with scale.

GLOBE ARTICHOKES.

CYANARA Hortensis is the Globe Artichoke of the garden. It is a hardy perennial and in this climate, an evergreen, growing from three to four feet high, with numerous branches. In rich soil the leaves will measure three to four feet in length, cut in deep, horizontal convex segments, which are covered with an ash-colored down, the whole plant resembling a large thistle. The portion eaten is the under side of the head, before the flower opens. The whole head is removed and boiled, the leaves laid aside, the bottom eaten, dipped in butter with a little pepper and salt. It is sometimes eaten raw as a salad. Sometimes the young suckers are tied together and blanched and served in the same manner as asparagus. Plants thrive best in deep rich loamy soil, although I have seen very thrifty plants in Southern California grown in adobe soil of the very meanest gumbo type.

They are usually set in rows three feet apart and about the same distance apart in the row. In the eastern states seed is usually sown indoors and the plants potted the same as tomato or egg-plant and set out into open ground in May. If well cared for it will make a fine growth the first season and some heads may be obtained during August and September, but the next year all the plants will flower and continue to do so for years.

In California the seed may be sown at any time and transplanted into open garden when six or eight inches high. It will mature in about eight months from planting the seed, but the usual time for blooming is during March.

If it were possible to get them to bloom late in the summer and fall they would doubtless bring fancy prices during the winter. I know of no method of doing this.

This plant is supposed to be a native of the South of Europe. The first account of its cultivation was in Italy in 1473, and from that period, when it was said to be very scarce, it has steadily grown in favor and its cultivation extended. There is a well-defined impression among eastern gardeners that a soil containing a large proportion of saline properties suits it best. Whether it would flourish in arid desert climate, I do not know, but it has always been successfully grown near the sea.

In two or three years the plants may get too large and should be divided into two or four pieces to the hill. This should be done here any time from December to last of January. Artichokes are not always satisfactory when grown from seed, owing to the numerous and undesirable types thus produced. One can secure a good stand by discarding the poor types and dividing the plants of the finer kinds and replacing the poor ones; but it takes time to do this. One ounce of artichoke seed will produce about 500 plants.— Q. A. Lobingier, San Gabriel.

"TIPPING" RASPBERRIES.

Many of our readers have some of the "cap" varieties of raspberries which they would like to propagate for another year's planting. For the benefit of amateur growers we will say that the "cap" varieties include such as do not propagate by root sprouts about the parent plants. These include all the black raspberries and the purple sorts. They are easily tipped but the work must be done in season, which is during the month of September. In fact, the plants are ripe for tipping any time after the summer's growth of wood drops, so that the terminals touch the earth.

We use a spade to open the soil by plunging the blade downward and pushing the handle forward until an opening is made in the earth in the rear, and after inserting the tip, withdraw the spade and press the soil firmly about the prospective plant with the feet. The tip should extend into the ground to moisture, or about three or four inches, where it will soon form a bunch of vigorous roots when they become an independent plant. These can safely remain where they started until spring, or may be dug out and "heeled in" or put into storage for next season's use. One good, vigorous bush thus treated will make a dozen or two of plants for the following year. If the fall happens to be very wet, some of the tips will root simply by coming into contact with loose sod.

Black raspberries are more dependable than the red varieties as far as yield is concerned, but as a rule are not quite as hardy. Every farmer's garden should contain a variety of fruits and vegetables.—Northwest Pacific Farmer.

WARDING OFF THE CUT WORM.

The grower of all kinds of vegetables will soon have to be on the lookout for the cut worm. A knowledge of a few essential points to control and destroy the pest will save each grower much money if practiced. I take a newspaper and cut it into squares of about two and one-half inches. After the plant is partially imbedded I wrap this slip of paper closely around the plant, making sure that it will be no less than from three-quarters to one inch above the ground when leveled around the plant. This I leave around the plant about 10 days to two weeks, or until the plant is sufficiently hardened and proof against worms. Then I take care that these paper slips are ripped off, as I lost some plants once by the paper sticking so closely that it killed the plant.

The Ornamental Garden

THIS MONTH.

SET all deciduous trees and shrubs into their permanent location at once. Roses, vines, sweet peas, annuals should be planted. Amongst others, ageratum, coxcomb, balsam, zinnia, snap dragon, and other summer flowering plants. Pot bulbs of gloxinia, gesneria, tuberous begonias and fancy calladium.

The lawn needs trimming and fertilizing and a good rolling will benefit it.

Don't neglect pruning off the straggling ends of the ornamental trees.

PLANTING OF PERENNIALS.

Every one admires flowers. Children delight to gather them. Artists gather inspiration from them. Their artistic blending of colors inspires us to admiration for the beauty of nature, and we delight to see them in the landscape. If they are properly placed in the planting of the home grounds, they add much to the attractive features of the landscape picture. The place for them is not in the center of the lawn, but at one side, where they may have a background of shrubbery.

But only the hardy ornamental perennials should be used for this purpose. If perennials or annuals are wanted for some special purpose or cut flowers, they should be grown in a place by themselves where they can be cultivated, the same as vegetables. The perennials are flowers which once planted are ever present. There are a large variety of these perennials from which selection can be made, which will give flowers in abundance throughout nearly the whole year. Some of the best include Phloxes, Gaillardias, Pyrethrums, Irises, Delphiniums, Foxgloves, Poppies, Rudbeckias, Sunflowers, and a host of others. Some of these should be planted among the surroundings of every home.—L. A. Times.

MASSING OF SHRUBS.

All shrubs and flowers should be planted in masses of several plants of a variety in a group. They should be planted close enough together so that we do not see the individual plants but the group as a whole. The distance apart will depend upon the ultimate size of each variety. Thus most of the perennials should be planted a foot apart, while the proper distance for shrubs varies from two to eight or ten feet. A mistake of too close planting is much better than otherwise, for we can then thin out if necessary. If our means are so limited that we can afford to have but a half dozen plants, they should all be placed together in a single group rather than to make the common mistake of planting them here and there as individual specimens in the lawn. Grass and shrubs do not do well together, but when the shrubs are planted in masses the ground can be given up to them and no grass allowed underneath. All the care required is an occasional stirring of the top soil in order to retain the moisture and prevent the growth of grass.—Los Angeles Times.

A big corporation is contemplating a big eucalyptus plantation in Glenn county.

TO KEEP PANSIES GROWING.

Soapy water used on the pansy bed is said to cause blight that kills the plants in a short time.

Try cutting almost the entire top off the straggling pansy-plant in July keeping it as dormant as possible during the hot weather, then dig a little fertilizer in about the roots, water well, and in a short time the plant will begin to bloom abundantly.

When the pansy plant begins to sprawl, gather the plant up in a bunch, dig up the roots and dig a hole deep enough to set the whole plant in, so the crown will be about an inch or so below the surface; press the soil firmly about the plant, with the branches held closely together in a bunch; cut off about an inch of the straggling branches, and the result will be a fine, stocky plant for fall blooming.

Keep the blossoms picked freely from the pansies. If allowed to perfect seeds, the plant will cease blooming. Nature seeks always to provide for a succession, and this being done, the life work of the plant ceases. This is so with nearly all free-flowering plants.

CUTTINGS.

Gardeners have good luck this month rooting cuttings of carnations in clean, sharp sand; young brittle tips are selected, broken off or cut with a keen knife, and set firmly in the sand just deeply enough to hold themselves erect. As soon as rooted well, they should be potted in soil.

Hardwood cuttings of roses, if made now are pretty sure to root and so will hardwood cuttings of lilac, crape myrtle, hydrangea, deutzia and other dormant shrubs and trees. The cuttings should be made long enough to have three or more eyes and be set firmly and deeply in sand box or the ground, leaving one or two eyes above the surface. A partially shaded position is best.—Pacific Garden.

NOT SO BAD AN EXAMPLE.

The Denver Field and Farm says:

"The irrigation district idea which proved such a holocaust in California twenty years ago is working all right in this state and if we can only rock along a few years longer without a pettifogging legislature dipping in on us the cloth will cut all right and make a warm garment. Almost three-quarters of a million acres have been and are being reclaimed through the agency of the district law and nearly $15,000,000 in bonds have been issued. Not a dollar of interest has been delinquent and the work of district development in the state otherwise practically impossible has but fairly begun. The men who drew up the law creating these districts made a careful study of the Wright act which brought so much grief upon California and with such a horrid spectacle for a guide they were enabled to steer clear of the shoals and the result is a law entirely satisfactory to everybody connected with it. The horror of a bad example is sometimes a good lesson."

It may be admitted that the Wright act was handled so as to cause great loss in some districts, but that was not because it was a bad law. Where understood and properly handled it has given satisfaction and is the cause of some districts' prosperity so they are today adding to the wealth of the state.

METHOD OF PROPAGATING EUCALYPTUS.

FROM Bulletin 196 published by the State Experiment Station and written by Norman D. Ingham we quote as follows of the method of propagating and care of young seedling eucalyptus plants:

The Propagation of the Seedlings.

The necessary conveniences for the propagation of the seedlings are as follows: seed boxes or flats, a good soil, seed true to name, plenty of water convenient to all flats, and in most localities a shade for the young plants from the sun is required.

The Flats.

Boxes can be bought very cheaply from the grocery stores, that will make, when sawed up, flats of varying sizes; flats in the shook, sawed to any size can be bought from the box factories at a very reasonable price. Flats 22 by 16 inches in size, outside measure, will hold one hundred transplanted plants, although they can be made larger or smaller and handled practically as well, but the depth should not be over three inches, so that the roots of the young plants will have a tendency to spread out, instead of forming a long tap root that is liable to be either cut or broken off in transplanting.

The Soil for Seed-bed.

It has been proven that eucalyptus seeds will germinate and grow in nearly any soil, from a clear beach sand to adobe, but the best results are obtained if the seeds are sown in a light loam, while a medium loam mixed with about one-fourth well-rotted horse manure should be used in the transplanting flats.

The Seed.

When buying the seed, care should be taken to deal with reliable seedsmen, for otherwise a season's growth may be lost by sowing seeds not true to name. Eucalyptus seed can be bought at from $4 to $15 per pound, according to the species and the seedsman's reputation. In many localities seed of a few species can be gathered, such as the common Blue Gum, Eucalyptus globulus, the Manna Gum, Eu. viminalis, the Swamp Mahogany, Eu. robusta, and a number of others that are scattered over the state.

The Amount of Seed to Buy.

The number of fertile seeds of any species to the pound is very high; the average number of transplanted plants raised to the pound is 12,000.

The seed of most species can be gathered at all times of the year, although the greater amount mature during the summer and fall. The seed cases should be gathered from the trees when the valves begin to open and placed on sheets of canvas or blankets in the direct rays of the sun, which will open the valves, allowing the seed and chaff to fall out.

Shade for Young Plants.

Where a large number of plants are to be grown, a lath house, with the lath spaced their own width apart for the protection of the young plants from the midday sun, will be found more convenient than lath or cheese cloth screens laid on small frames above the flats, as the labor required to move them each time the plants are watered would amount to a large item of expense during the growing season. The lath house or the screens will also protect the seed flats from the ravages of the birds and the young plants from the frosts (if not too severe) during the cold weather of the winter months, before the time for setting in the field.

The size of a lath house for a desired number of plants can be figured out, twenty-eight transplanted plants to the square foot, or an area of sixty feet square will hold one hundred thousand transplanted plants and allow ample room to go among the flats to water them.

The Time to Sow the Seed.

The time to sow the seed varies somewhat with the locality, but as a general rule the seed should be sown by the latter part of June or first of July, and the seedlings from these sowings will be large enough to be set out in the field the following spring, if they receive proper care while young.

Methods of Sowing the Seed.

The seed is generally sown broadcast in the seed flats and the young plants transplanted once before being set in the field, but some persons take the trouble to sow one seed in a place and space them in the flats. By this method transplanting is unnecessary, while others sow the seeds in hills and practise thinning, instead of transplanting, before setting out in the field. This latter method is used in some localities of the San Joaquin Valley with good success, because of the great trouble experienced in transplanting during the hot summer months in that region.

However, in the event of either of these methods being used to sow the seed, fill the flats to a depth of two and one half inches with the prepared soil, pressing it down firmly in the boxes, then sow the seed and cover them to a depth of not over one-fourth of an inch with the same soil, sand or sawdust, pressing this covering firmly over them. The best results have been obtained at the Forestry Station by using sand, while the Experimental Forestry Company of Hanford, California, have had better results with redwood sawdust as a covering and mulch for the seed flats than with any other material.

Care of Seedlings.

The seed flats should be kept damp through the heat of the day, until the young plants break the ground, then care must be taken not to use too much water and that there is a good circulation of air over the flats, or the fungous disease "damping off" is liable to occur. Damping off is most general on damp, cloudy days and where the plants are watered late in the evening, as there is very little exaporation from the earth's surface at night. This disease can be prevented by using practically no water on cloudy days and only in the mornings on clear days. Some species most susceptible to damping off are as follows: Eucalyptus corymbosa, Eu. citriodora, Eu. calophylla, Eu. ficifolia, Eu. globulus.

A KING COUNTY REAPING SCENE.

YOUNG MEN WANTED

Live Stock and Dairy

Dairymen and stockmen are requested to write of their experience. Mrs. Sherman is always willing to answer queries and this, with experience of other workers, will make this department of greater value.

By Mrs. Minna E. Sherman

ALFALFA AGAIN.

THIS season as well as last season, the Weather Bureau people have handed the farmers a series of problems to solve rather than seasonable changes. I do not believe any one of us will ever live to have another season that will prove as perplexing and upsetting to all calculations as this one. There are, however, a few fundamentals in farming that must never be overlooked no matter what the season may bring forth. One is that soil must only be worked when it will crumble behind the plow. When the land is too dry it is wasting time to plow at all; when it is too wet it is not plowing but puddling for brick-making. The clods made by plowing wet land will take several years to break down into good condition of soil tilth again. They make the land unsightly and also reduce the productiveness for the time. Farming just now is a scramble to do the things in a hurry that the rain has made impossible to do in their proper order. Only faith in God keeps the farmer from giving up at times. It has been said that three-fourths of the requirement to make a farmer is clear grit, the other quarter is knowing how to do the work.

Dry Lands.

Alfalfa is often successfully sown on land that cannot be irrigated and in wet seasons a full stand is secured. Success in making a catch of the seeding last season was not good in many places; this season is wet enough to fill out these fields. As soon as possible to do so, disk the land to make the division of the crown while the season is cool. Set the disks as straight as possible and have them sharp enough to cut, not tear their way through the plants. When the weather is a little warmer, sow the thin places and harrow in well. Harrow in a cross direction, rather than the way the disks ran. The harrow will throw some loose dirt on the cut crown; this is rather an advantage to them as it covers the cut portions from the light. When the alfalfa plants are four years old, I do not hesitate to disk both ways. On younger alfalfa the crowns are rarely large and solid enough, and the cross disking leaves them small and weak. Attempting to disk when the ground is too dry is a mistake, for the roots are torn to pieces owing to the unyielding soil. The dry soil is not stirred so that the labor is wasted.

Foxtail.

When the alfalfa fields are full of foxtail and other weeds, the regular alfalfa harrow with its spike-like teeth to dig into the soil is used. Crossing the field both ways with this tool stirs the soil and weeds out the shallow-rooted foxtail. To do this successfully the soil must be moist and it will then be made loose and friable. Making the soil loose after the last rains greatly helps the crop of hay. The use of the spiked tooth harrow on many soils proves profitable when it is used after each cutting of alfalfa. Where it is run in this way the soil remains open and light on the surface. On irrigated alfalfa it is even more necessary than on those that are dependent on the roots reaching down to moisture. This in a way may be considered a dust mulch, the same as the horticulturist insists on in the orchards and vineyards of the state. Remember this labor is useless in cases where the land will not crumble readily. One of the most important things we can do is to make this condition possible, for there is a way that the land can be made to stay open, and that is by adding humus.

Humus Making.

The addition of manure to alfalfa land is furnishing it with humus, while adding gypsum to that manure is to increase its availability. Humus is a name for the organized matter of other plant life in a form that is at once food for other plants. While plants can make their own food from the soil, air and water, if we present it to them in a more available form we gain more rapid growth. In dry lands humus becomes a conserver of moisture. It might be better to put that into a little different form and say that humus acts like a sponge to hold moisture and that it will hold soils in a good friable condition long after the soil devoid of humus is baked into a hard mass. When humus is abundant it is not possible for soil to bake. Humus laden soils will hold fourteen times as much water in them as the soil without humus.

Gypsum.

In handling alfalfa on dry land there are often spots that are annoying by failing to grow while all the rest of the field yields well. The same trouble often appears on fields that are pastured too long. These spots should be manured, using gypsum with the manure. A sack of gypsum sprinkled on the top of every two-horse load of manure is a simple way to handle it. Spread the manure about four inches thick over the bald places in the fall or winter time and after it has been rained on plow under four inches deep, harrow again, and when sowing time comes seed again. Then disk the whole field.

Opportunity.

A wet winter like this is the opportunity to bring into fertility all the bad spots on the alfalfa fields. The secret of successful farming is making everything count and doing no useless work. The tax collector makes no allowance for the bad spots on the fields. The mower crosses them and yet they pay no returns whatever. There are other things coming to us soon to help the producer of alfalfa. At the Tulare Station Dr. Shaw has many varieties of regional alfalfa under tests. Three of these were brought from the field to the demonstration train at Tulare last week. The common alfalfa was seven inches tall, while the Turkestan was 14 inches, and the Arabian was 22 inches all grown since last December. As Dr. Shaw expressed it to his audience, it was adding a story to the present yields, making a two and three story structure of the common alfalfa. Per-

What the
WORLD'S BIGGEST USERS
Say About
CREAM SEPARATORS

Lincoln, Nebraska, November 11, 1908.

When we first began in the creamery business we operated several hundred skimming stations and had in use a large number of the various makes of power separators. Owing to the all around superiority of the De Laval Separators we found it necessary to replace all other makes with the De Laval and this proved one of the best investments that we ever made.

During the years 1901 and 1902 the hand separators came into very general use and our thousands of patrons naturally looked to us for advice as to the most efficient and most durable separator for them to buy. Realizing the necessity of preventing, if possible, the sale of the so-called "just as good" and "cheap" separators we secured the agency of the De Laval. With the wonderful record back of the De Laval machine, together with the positive proof we could show by actual demonstration, we were able in a few years to sell from twenty-five to thirty thousand of the De Laval Hand Cream Separators, and we are pleased to say that they have given universal satisfaction and are still in use, while most of the so-called "cheap" separators that a few of our patrons were foolish enough to buy have found their final resting place in scrap pile.

At the present time we are not agents for any hand cream separator, but for the future good of our own business as well as the dairy industry, we are naturally anxious to see every dairyman who buys a hand separator buy the machine that will prove the best investment in the long run, and wide experience has taught us that when it comes to efficiency, durability and hard knocks the De Laval Hand Cream Separator easily stands in a class by itself. haps many of you may not know that the University is cultivating in the different parts of California nearly a thousand acres of land in alfalfas, wheats, barleys and other cereals! That the increasing yields of these selected varieties promise to double the present yields! That the careful selection of wheats is now at the point where the millers will not be obliged to import wheat for flour, This seed will soon be ready so that California will be able to grow her own hard wheat. I will try to tell you next week about the trip on the Demonstration train. At every station nearly, I found readers of the Cultivator eager for information in a practical way on the pruning of the grape vine. It was a pleasure to hear the many pleasant words spoken in praise of the Cultivator as a practical farm paper.—M. E. Sherman.

THE FOOT AND MOUTH DISEASE.

Concerning this disease, Dr. Smead of New York says:

"All of the cloven hoofed animals are more susceptible to the contagion than the horse or several toe footed animals. This is no doubt due to the germ or virus being conveyed by moist soil or filth containing it up between the sections of the bifurcated foot to the skin just above the foot, which is the point of inoculation when it is moist or perhaps a little sore or tender. A pustule is soon formed which produces a violent itching. The animal licks it to get relief and then the mouth becomes affected and blisters and pustules soon appear. The whole system becomes more or less fevered. The animal is unable to eat any solid food, and unless it is furnished nourishment in a liquid form will likely starve before the disease will run its course as an eruptive fever, which lasts from ten to fifteen days. If the animal survives, it is practically immune from the disease ever afterward. In extremely bad cases where nothing is done to alleviate the disease the hoofs sometimes drop off.

The milk of all cows suffering from this disease is wholly unfit to use for either human or animal food; also the flesh is unfit for human food; yet the danger of conveying the disease to the human by the use of either the milk or flesh is extremely doubtful. There are on record a few cases where it was thought to have been thus conveyed; but the chief source of human infection is direct inoculation of the poison or germ entering the system through abrasions of the skin or sores on the hands.

It is not a very fatal disease in animals, the loss being largely from dairy herds becoming worthless, the loss of hoofs of other animals, and—worse than all—the soil where the animals run becoming inoculated to the extent of making it a source of continual danger. Therefore, all cattle, sheep or swine owners, on the first appearance of disease of the nature described, should do their utmost to stamp it out. Our federal government has been very alert and generous with the livestock owners of this country, and has thus far deemed it better and safer for the country's good to buy all ailing animals and pay for them; also to disinfect, or aid the livestock owners in disinfecting, their premises; and it becomes all livestock owners to aid the state and national governments all they can in their work of preventing this disease from ever getting a foothold in this country, even if for a short time a rigid quarantine has to be enforced. The germs or virus—whichever it may be—can be conveyed in men's boots, by dogs, cats and fowls. Therefore, don't hesitate to keep the animals shut up whenever there is an outbreak, and usually a week's time will stamp it out when properly managed.—Hoards.

NEED OF CAREFUL MILKING.

Every milker thinks he knows how to milk, but if the cows could speak, they would probably intimate that a few lessons in the gentle art would not be out of order. It is not fair treatment to sit down to a cow and tug and haul on her until the steps around in the stall and acts as if she were badly hurt. Sometimes a cow will stop eating and wait until the ordeal is over before she will resume her meal. The cow that does that is usually not comfortable, and an uncomfortable cow will not do her best. Some men have a way of milking that so pleases the cow that she clearly shows her satisfaction. These are the men whose methods should be studied. They never shout at, strike, or otherwise ill-treat their cows. They sit down quietly, take hold of the teats gently, no matter how much of a hurry they may be in, and begin to draw the milk without pressing too hard, for they know they are touching her at a tender point. Then they keep steadily at it until the last drop is out. There is no excuse for having a kicking cow in the herd. The kicking cow is almost always made so by her attendant. If a cow is handled before she comes in so as to become familiar with her attendant, and has been kindly treated, there will probably be no trouble.

It is my opinion that in nine cases out of ten, where there is trouble of this kind, it serves the attendant right to get a good kicking. I think if all milkers would do a little thinking, a little sound reasoning, and investigate matters a little, they would probably find sore teats a common cause for a kicking cow. Instead of using the much-talked-of straps or ropes, I should advise them to use a good remedy. One which has proven effectual without a single exception is simply clean lard. About 15 or 20 minutes before the cow is milked the first time, the lard should be applied to the teats, and when through milking wipe the teats perfectly dry with a soft dry cloth and apply the lard again. This was usually found necessary for about five or six milkings. Many milkers have the bad habit of wetting their fingers when milking, and when the teats of young cows are left in this condition, they get sore. On the other hand, lard heals or takes away the soreness that is so natural, caused by the action of rough, hard hands upon the teats that are not accustomed to the milking process.

I once visited a farm where they had a fine young Holstein cow which has just freshened for the first time. The milker and the poor animal had gone through almost everything during the first three milkings. The cow had no means of expressing her sufferings except with kicks, and the owner, though a kind, intelligent person, could not think of other methods to apply except what he had used so often with other cows—tying her with straps or ropes. He decided then to let her keep her calf, as it seemed

Try this for a Big Load

The easiest running wagon or dray is the one lubricated with Mica Axle Grease.

Kills friction; stops wear; makes a two-horse rig run with one-horse power.

MICA Axle Grease

contains powdered mica which coats the axle with a non-friction surface—*that's* the *why* of it.

No grease helps as much as Mica Axle Grease.

If you try it, you'll know it.

an impossibility to milk her. It was then that I happened to have my attention called to it, so I told him of our method which at that time we had tried only with three or four young cows. He laughed at me when I suggested that I would apply the lard myself. But the poor cow's teats were now so sore she would not even let the calf touch her. With considerable patting and rubbing and kind words I had the satisfaction of getting the lard applied, and the still greater satisfaction of seeing the cow stand perfectly still a short time afterwards to the great astonishment of those present.

The cow is a creature of habits, and upon the attendant depends the formation of these habits. The more regular they are the better work she will do in the dairy. Teach the young boys to be kind to the cows, to feed them properly, and do everything in their power to make them contented and happy. The true dairy cow usually possesses a highly nervous temperament, that rebels against harsh treatment. In view of this fact it is ill-advised economy for the dairyman to share with the farm dog the duty of caring for her, for if he does, she will in all probability even up with him by giving an ever diminishing quantity of milk. Gentle treatment is about as important as good feeding, and must be the practise of dairymen if they expect to succeed.—Kimball's Dairy Farmer.

STOPPAGE OF THE BOWELS IN CATTLE.

This is one of the most common ailments that cattle are subject to; at the same time more cattle die from this cause than any other, for the simple reason that stoppage is due to paralysis of the bowels.

Stoppage of the bowels is to be regarded as a sign of another disease rather than a disease itself. It occurs in almost all fevers, indigestion and over-eating.

In order to overcome stoppage of the bowels a treatment must be applied to overcome the ailment which causes it, such as paralysis of the bowels. Seventy-five per cent of the cases of stoppage of the bowels are due to partial paralysis of the bowels. In this case the bowels require a laxative and tonic and not a physic, for if the bowels are paralyzed a physic will have a tendency to cause irritation, indigestion, inflammation, and death follows. For this reason it is dangerous to give a cow salts or oil.

A cow thus afflicted should be given a laxative and tonic, plenty of drinking water, with the chill taken from it, bran mashes made of flaxseed tea, also inject several quarts of warm water once or twice daily through the rectum by the use of the hose and funnel, and give the animal a reasonable amount of exercise.—Dr. David Roberts, Wisconsin State Veterinarian.

Have little bedding in the pen at farrowing. Wait until the pigs get large enough to take care of themselves before bedding heavily. Have the pen dry and clean and keep it thus. Make liberal use of the well-known disinfectants. Prevention is cheaper than cure.

Before calving the cow's food should be reduced in quantity and of a laxative nature.

Made of wire that is all life and strength — wire that stretches true and tight and yields just enough under impact to give back every jolt and jam it receives.

Made of materials selected and tested in all the stages from our own mines, through our own blast furnaces and rolling and wire mills, to the finished product. Our employment of specially adapted metals is of great importance in fence wire; a wire that must be hard yet not brittle; stiff and springy yet flexible enough for splicing—best and most durable fence material on earth.

To obtain these and in addition apply a quality of galvanizing that will effectually protect against weather conditions, is a triumph of the wiremaker's art.

These are combined in the American and Ellwood fences—the product of the greatest mines, steel producing plants and wire mills in the world. And with these good facilities and the old and skilled employes back of them, we maintain the highest standard of excellence possible for human skill and ingenuity to produce.

Dealers everywhere, carrying styles adapted to every purpose. See them.

AMERICA A GREAT MARKET.

A Texas subscriber kindly sends us a copy of the San Antonio Daily Express in which the possibilities of Mexico as a producer of tropical and semi-tropical fruits are referred to. The paper says: "Statistics show that in the year 1907 the United States imported tropical and semi-tropical products to the value of $567,166,242 gold or $1,134,332,484 Mexican currency, and that in this enormous importation Mexico, a country directly at its doors, had but a small share. Here are some of the facts brought out:

"In 1907 the United States imported tropical and semi-tropical fruits and nuts to the value of $37,040,689 gold. Mexico's share in this amount was $189,641. In 1907 the United States imported coffee to the value of $76,534,808 gold. Of this amount Mexico received $1,697,094. In 1907 the United States imported cacao (chocolate) to the value of $14,578,989 gold. Mexico sent just $11 worth.

"The details of the fruit importations show that in the year under discussion the United States bought bananas worth $11,872,283 gold, and that but $10,884 of that amount came from Mexico; that the lemons purchased had a gold value of $4,250,979, and that Mexico participated to the extent of only $2317; that the value of the oranges imported was $309,316 gold, and that Mexico's shipments amount to only $45,179, and that out of $1,342,879 gold paid for cocoanuts Mexico received but $6683.

"That Mexico can produce bananas, lemons, pineapples, oranges, cacao, cocoanuts and coffee of superior quality, and that an immense trade should be built up in these products between the United States and this republic are two points brought out by Mr. Mallen in his book."

In the same issue account is made of the efforts of the Eastern importers through the New York Fruit Exchange before the Ways and Means Committee for free trade, especially on lemons, but in a general way on all semi-tropical fruits. Now the question before our American producers is, will the greatest market of which the world knows be turned over to the New York importers for the benefit of European fruit producers and incidentally for the encouragement of a great industry in Mexico, or will it be retained for our own people, that greater comforts may be had by them and that our own wealth may be produced?

We have seen the statement that if the lemon importation of the United States could be terminated and those same lemons produced in this country, it would give employment and be the means of establishing five thousand more homes in this country. "While the production of American lemons has increased during the past ten years, the percentage of homegrown fruit consumed in the United States has not materially increased. In 1901, 67 per cent. of the consumption was imported; in 1907, 64 per cent; in 1908, 2,231,125 boxes of lemons were imported into the United States, which was the heaviest importation in the history of the business and was an increase of over 400,000 boxes in excess of the importation of 1901. It is still more important to the whole people of the United States that this very necessary article of diet be produced at home, to the end that the supply would be insured and that the prices be freed from the control of a foreign nation or the opportunity for combination of a few large importers.

KNOWLEDGE AND EXPERIENCE.

The rosy hued literature which is sent out from California to induce Easterners to purchase our land and make this their future home, while as a rule telling the truth does not always tell the whole truth. Or at least, often, it has been known to give wrong impressions as to the ease with which farming or fruit growing work is taken up in California.

California soil and climate when supplemented with irrigating water certainly does accomplish wonders in producing wealth. But to give people the impression that the situation here is such that any one can without material effort supply the conditions necessary to make this wealth is, we believe, unfortunate.

True, the shrewd man may say that no one should expect to come here and take up a calling entirely different from that which he has been following in the East and succeed without hard study and close observation of our methods of work. We do not think that the people who are so zealously engaged in promoting the sale of real estate give this wrong impression wilfully—rather through not fully understanding the difficulties against which the Easterner is forced to contend. We have known of people coming here whose life has been spent in the professions and who expected to at once take up farming without giving its details any due consideration. Where the newcomer has done this without understanding, the only salvation for him is to open his eyes very wide and see how his neighbors who are succeeding conduct their farms. Too often, however, the newcomer has an idea that the former settlers are inclined to be back numbers. Possibly this may be true in certain cases, but the older farmer certainly has some ideas which would be of value to every newcomer.

Nor is the farmer who has had wide experience in the East fully qualified to take up the work in California. Conditions are so vastly different that they must be understood from the California standpoint if success is to be secured.

We would not have our newcomers believe by any means that the farmers now located here can supply them with all the information necessary. In fact those same farmers are the ones who today are putting up a loud call for better agricultural education for their children in our public schools. They realize the handicap under which they are laboring and feel that the necessity is imperative for better qualifications for the future farmers.

THE WATER.

The office of experiment stations is sending out Bulletin No. 203 of Irrigation Investigations by Dr. R. H. Loughridge of University of California. This bulletin contains the results of observations upon the percolation of water in the soil beneath the furrows in which water is applied to orchards in the vicinity of Riverside. These observations were made as a part of a study of the losses of irrigation water and their prevention. In the vicinity of Riverside the available water supply has been put to use, and further expansion of the irrigated area depends upon more economical use of this supply. Canals have been lined to prevent seepage losses, the orchards are intensively cultivated to check evaporation losses, and this study was undertaken to arrive at some knowledge as to the losses by percolation, with a view to taking steps to lessen them if practicable. It does not, however, go into the question of methods of checking these losses. The report contains the results of observations on a number of orchards, the results showing clearly the great necessity of each orchardist examining his own soil and subsoil conditions and adapting his methods to these conditions.

AGRICULTURAL HIGH SCHOOL.

In another column of the Cultivator may be seen an article written by Mr. Mark R. Jacobs. Mr. Jacobs is principal of a high school located within the limits of the city of Los Angeles, but being in an outlying rural section has been encouraged by the Board of Education in its effort toward studies which point to nature and to the life with which the farmer comes in contact. Fortunately, the school has fallen under the principalship of one who is enthusiastic or at least deeply interested in things agricultural.

True, the effort is only just taken up, so that no lesson can be drawn from its accomplishments. but we may at least point to the effort and hope it will encourage those in charge of other schools of the state to make similar effort.

The Holstein-Friesian Association of America is offering prizes which will be given at the Alaska-Yukon-Pacific Exposition to be held at Seattle next summer, which will aggregate $500 in value. The same organization will give a $25 silver cup for the fair to be held in Spokane next fall, also a silver cup of like value at the State Fair at Sacramento. We notice the account says that eastern state fairs at Springfield, Illinois, Syracuse, New York, and other sections, will be granted $500 in prizes. This looks as if the Pacific Coast is not in the same class with the Eastern states in the eyes of the Holstein-Friesian people.

"First rude vigor, then tempered strength, then a great human spirit touched with the pathos of infinite patience and sorrow; an ideal American who had climbed from the bottom to the top; who had educated himself by the way, and in becoming supremely great had remained supremely human." That was Lincoln.

No authentic information is given out, but rumor has it that the Ways and Means Committee is to place lumber on the free list. We do not think the fruit growers of the state are making any particular fight for free trade on anything, but stand in the attitude of being wonderfully willing to have free lumber for fruit boxes, trays, and general building purposes.

From data compiled by W. C. Mendenhall, there has been drawn and printed an excellent map of the San Joaquin valley of California. It shows the artesian areas and ground water levels over the entire valley from Tehachapi to Sacramento. The map is known as Water Supply Paper 222 Plate 1.

Agricultural Notes of the Pacific Coast

Northern California

It is predicted that wheat will be a light crop and high priced during the coming season.

Dairymen in the Loleta section, Humboldt county, are organizing a cow-testing association.

Premature blooming of almond trees it is feared may bring disaster upon that crop this season.

It is stated that there are 300,000 boxes of apples in cold storage in San Francisco at the present time.

California butter makers are hoping to secure a contract for a quarter million pounds of butter for the navy.

The Sacramento valley has more water power within its limits than all other sections of the state combined.

Much of the land that is now flooded along the rivers is expected to be dry enough for later spring crops.

The Ferndale Co-operative Cow Testing Association is now fully organized with nearly 30 dairymen as members.

The Farmers Storage Company of Colusa now has a greater warehouse capacity than any other company on the Sacramento river.

Crude oil coating applied to the sides of the levees has been proven during the recent floods to be effective in preventing the wash.

The storms in the Sierra Nevadas have driven down many deer which have been seen in the lower foothills, some even in the settlements.

The Game Farm, located near Haywards, is getting in shape for breeding several varieties of game which have already been established there.

Sacramento Valley Development Association has endorsed the proposition for bonding the state for $18,000,000 to advance the good roads cause.

A committee from the Yuba and Sutter Growers Association held a meeting recently at Marysville to discuss the scab bill now before the State Legislature.

The Colusa County Board of Supervisors has appointed a committee to confer with the supervisors of Yolo and Glenn county to fix upon an uniform coyote bounty for the three counties.

Stockmen in Waddington, Humboldt county, are compelled by the continuance of the storm to feed, and they are now hoping the storm will cease long enough that they may place their stock on pasture.

The bill before the State Senate known as the Price bill calls for an appropriation of $15,000 to promote the investigation of the vine and its enemies and general promotion of the viticultural industry.

The Sutter County Farmer reports that the prospects for a grain crop are the poorest on record, but the crop of hay will be abundant. The first cutting of alfalfa promises to be exceptionally heavy.

Many cows were drowned in the flooded districts during the recent floods. Some at Marysville which had been driven to the tops of the levees were stampeded by dogs, so that many after being saved were lost in their fright.

Central California

Apricots are in bloom.

The Fresno County Farmers Union is considering a proposition of an Eastern firm for 100 car loads dried fruit.

Raisins are now going forward at a more rapid rate than for some time and it is now hoped the old crop will be cleaned up.

Dinuba has recently had a raisin contest at which things cooked with raisins and raisins cooked in different styles were the exhibits.

The Farmers Union at Hanford is busy shipping fruit and the producers are generally impressed with the advisability of supporting this institution.

Delegates of the various Locals of Kings, Fresno and Tulare Farmers Union held a meeting last week at Kingsburg to perfect a district organization.

The County Veterinarian of Tulare county has posted notices announcing quarantine against movement of cattle from that county on account of Texas fever tick.

Producers of the Watsonville district are urging the necessity of deepening the channel of the Pajaro River up to Watsonville so as to give better shipping facilities.

The few oranges left in Sanger orchards in eastern Fresno county after the holiday shipments are now being cleaned up. All fruit is practically uninjured by the cold weather.

Representatives of large fruit buyers have examined many Kings county orchards to determine as far as possible at this early season as to the output of apricots and peaches.

An action brought by apple shippers for loss of apples carried over the Northern Pacific railroad, but which were not provided with refrigerator cars has resulted in an award for the shippers.

A Kings county raisin grower after keeping careful account of raisins fed to young growing pigs has figured out that raisins netted him as pig feed $36 per ton. This is better than some sales which have been made to the packers.

Many growers of the San Joaquin valley have gone east with their raisins and are selling them on their own account. The next step will be for several to stand together and reduce the expense of this kind of a campaign, or as now appears try the Union.

The Pajaro valley apple growers are making more strenuous demands for the erection of a cold storage plant. Success which has been secured with some apples which were shipped to storage plants show the gain which will accrue to the industry if a large plant may be had at Watsonville.

With all the warning which this state has had against introducing fruit trees from Florida and with the knowledge on the part of the grower that no living plant can be introduced from that State under the ruling of the State Horticultural Commission, such shipments are still attempted, and only last week at Lindsay a bunch of pecan and persimmon trees shipped from Macclenney, Florida, were ordered burned.

Southern California

Saticoy boasts of 22 inches of rainfall up to the present.

Imperial shipments of asparagus aggregate about $1,000 a day.

Imperial valley asparagus sold in Chicago recently at $1.25 per pound.

The bulk of the cantaloupe planting is already done in the Imperial valley.

Imperial valley is becoming one of the greatest dairy sections of this state.

Nine thousand three hundred acres of beets are already planted in Ventura county.

The asparagus crop of the Imperial valley this year is estimated to exceed $75,000.

Fruit packers at Redlands are urging the establishment of a pre-cooling plant at that point.

Beans, peas and other garden truck are being planted heavily at El Modena, Orange county.

A Brawley, Imperial county, farmer raised 35 bushels of corn per acre after removing his cantaloupe crop.

Imperial county claims to be the greatest county for irrigation in the state, also in any of the United States.

The cantaloupe acreage in Imperial valley is now reported to be about 3,000 acres short of last year's planting.

Stockmen all over Southern California are greatly elated over the magnificent feed with which all the hills are covered.

Eugene Germain, one of the oldest nurserymen and seedsmen on the Pacific Coast, died at his home in Los Angeles, February 18.

Beet planting is begun for the spring crops and thinning on the earlier planted beets has already begun at Oxnard, Ventura county.

Grain growers hope that the sale of jute bags will be regulated by the Prison Board so as to give more fair treatment to the farmer.

The success which walnut growers secured in last year's grafting operations will inspire extensive grafting over of seedling walnut trees this spring.

The big Bixby ranch near Long Beach, Los Angeles county, is shipping several cars of eucalyptus trees in flats. 56,000 trees are required to fill the car.

Many small tracts are being planted to the sugar beet in the Imperial valley in order to test the soil and see if a good content of sugar can be had in beets grown there.

Many Southern Californians are desirous of a return to the old name of the San Jacinto Reserve instead of the Cleveland Forest, which was the name given by President Roosevelt.

Riverside was recently favored with a shipment of Florida oranges, but as it was consigned to no one, visions of the white fly appeared and it was not long before the box and its contents were consigned to the flames.

A forest ranger in the Santa Barbara National Forest, unable to break his way through the snow to the Ventura postoffice was forced to travel across the mountains into the San Joaquin valley and mail his monthly report at Bakersfield.

The Coast

A heavy rain last week was a great aid to crops near Pullman, Washington.

It is rumored that onion growers near Portland have combined to boost prices.

Spitzenbergs and Yellow Newtons are the favorites with Oregon apple growers.

Cherry growers of Wasco county, Oregon, estimate a big crop for the coming season.

Hops have held fairly steady and no week passes but good sales are made at Portland.

The state president of the Farmers Union of Washington has recently organized five new Unions.

Arid lands aggregating 3,000 acres near Almira, Washington, are soon to be brought under irrigation.

Farmers of the dry farming section of the west have given up hope of the passing of the 320-acre dry farm homestead bill.

A 10,000 bushel sale of wheat was recently made at Pullman, Washington, the price ranging from 96 cents for Russian to $1.10 for Bluestem.

A huge irrigation project has been started near Grant's Pass, Oregon, which will involve the expenditure of $300,00 and irrigate over 9,000 acres of land.

The Local of the Farmers Union at Athena, Oregon, is increasing in membership continually and it is hoped it will include nearly all the farmers of Umatilla county.

The Spokesman Review estimates that the tariff on jute bags and burlaps puts a tax of more than a million dollars on the farmers of the Inland Empire alone.

Oregon prune growers are asking the reason why prunes at this time are commanding so low a price when the crop in hand has been reduced to practically nothing.

Wool buyers near Pendleton, Oregon, have combined and it is feared by the growers that they will not be able to secure from them reasonable prices for the coming clip.

An enthusiastic meeting of fruit growers was recently held at Salem, Oregon, at which it was voted to form the Salem Fruit Union with a capital of $6,000. The object is to handle the produce of the members.

The Oregon Pure Bred Live Stock Association held an important meeting at Portland recently, at which questions of tariff as affecting stock breeders and many other points in live stock development were discussed.

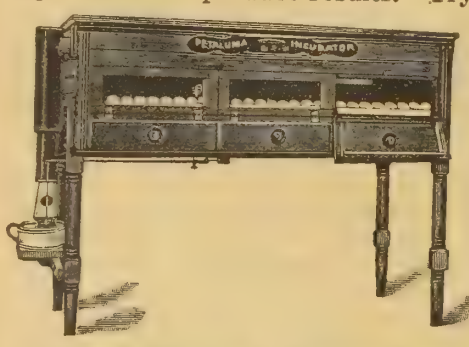
Four hundred farmers of the Inland Empire representing the State Farmers Educational and Co-operative Union, recently held an important meeting at Spokane, discussing the marketing of grain through one man or committee. More than 75 per cent of the producers were present.

The Grand Canyon Electric Light & Power Company has awarded contract to the National Wood Pipe Company, Los Angeles, California, for 15,000 feet of 4, 6 and 8-inch Machine Banded Redwood Pipe with cast iron collars. Contract also includes fire hydrants, and fittings. A complete water system will be installed.

Don't Forget Quality

MIDLAND Poultry Food

Is based on ***quality*** and it is quality in Poultry Food that produces eggs. ***Cheap filler*** and ***cheap grain*** will ***not*** make eggs. ***Midland Poultry Food*** contains only the ***choicest*** cereals and animal food the market affords. You ***can't*** afford to try and be successful and not get results. ***Midland Poultry Food*** will produce results. Try it and see. $1.95 per sack



Petaluma Incubators and Brooders

Are still here, after others are gone. ***The Standard of the World Machine.*** Winners of ***more prizes*** awarded by ***World's Fair Judges*** than any other make.

Remember, we make a hot water machine. One of the ***best hot water machines*** on the market.

Berrar & Robertson, 103 East Santa Clara St., San Jose, Cal.

"Chicks Well Hatched are Half Raised."

San Jose Hatchery, San Jose, Cal.

ANNOUNCEMENT

We stand for strong, healthy chicks and will spare no efforts to secure them. Our aim is quality rather than quantity. From the eggs we hatch we want the best chicks that can be secured. We shall limit our capacity to 12,000 eggs—six of our 2,000 egg incubators.

Three factors in securing chicks are—the breeding stock for hatching eggs; the incubator and the man to do the work.

We take great care in selecting our breeders from which we secure eggs. The stock must come up to our standard. Our Mr. Langenschwadt attends to this. He is a practical poultryman.

The incubator we use has been tried out and demonstrated for several years past what it can do. We consider it the best we have come across so far. The success poultrymen are having with chicks it hatches is proof sufficient.

In Mr. Henry Langenschwadt, our manager who attends the incubators, we have a man whom we are satisfied understands his business and he is demonstrating this by results.

At present can furnish following breeds and shall add to them as we can secure stock. All from utility stock:

White Leghorns we hatch regularly in two grades—No. 1 and special. Will hatch lower priced to order but cannot recommend them.

No. 1. White Leghorns: $9.00 per 100; $25.00 for 300; $40.00 for 500; $75.00 for 1,000.

Special White Leghorns: $12.00 per 100; $34.00 for 300; $55.00 for 500; $105.00 for 1,000.

Brown Leghorns, $10.00 per 100. Black Minorcas $12.50 per 100.
Rhode Island Reds, $12.50 and 15.00 per 100.
Barred Plymouth Rocks, $12.50 per 100.

Lots of 50 add one cent each. Less than 50 chicks do not recommend to ship.

Address orders to **SAN JOSE HATCHERY,**
395 East St. James Street,
Henry Langenschwadt, Manager **San Jose, California.**

Profit in the Poultry Yard

By Mrs. Frank Metcalf

We solicit short articles of a practical nature from the fancier and utility breeder, giving their experience with poultry. All inquiries pertaining to feed, management, disease and its prevention will be answered through these columns.

POULTRY AS SCAVENGERS.

THIS part of the usefulness of a few chickens is often lost sight of in the dread of their well-known destructive tendencies where flowers are concerned and gardens unprotected; but a half dozen or so can almost earn their own living where vacant lots adjoin one's premises, and keep said lot looking better than it would without their presence.

If no lot is available, an hour's freedom with a little watching will do them worlds of good, and they will find many tid-bits going to waste. I have my own yards so arranged that one flock has access each day to a back yard sowed to barley and alfalfa, and on the other days often let one lot out for a run about the house and garden. Sometimes they nip off a choice flower, or eat some particularly tempting bit of garden "sass," but with a little watching, they behave nicely and do worlds of good around the barn.

No need of a patent manure spreader where a flock of hens can swarm over the manure pile. They scratch it fine enough, and find plenty to reward them. The good man often says things which would not sound well in polite society when they get inside the barn and make themselves at home, but it is well to learn to shut doors after one, and he is learning the lesson slowly.

You remember "Samantha" encouraged the wife of a bashful man by telling her that "she wouldn't wonder if got so by the time he was 80, that he wouldn't get over a fence to get out of the way of meeting a woman on the road." So perhaps our men will learn to shut barn doors after them by the time they are 80 or so, if I let the chickens out as a gentle reminder occasionally.

INCUBATION CHAT.

Am afraid hens won't set early enough for good broods of early chicks, so will set up an incubator, and my boy conceived the idea of doing away with the legs and attaching it to the wall by hanging it on brackets. This seems a very good idea, as it will do away with the floor jar, and no legs in the way so a table can be set under if wanted. I have never wanted an outside incubator house, as I want them where I can see them at all hours without taking extra steps, so am setting it in the screen porch, in a corner that is solidly walled in. This insures fresh air, and although the thermometer may vary some, so do eggs under hens vary in degree of heat, yet still hatch, so that don't worry me very much. Just so the heat don't go up, and there is a new contrivance on the market (there used to be such an attachment to old machines) which will ring a warning bell if the heat varies inside the machine, that I may test later on.

I have found that when eggs are placed in a large pan of water at 103 degrees for an hour or so before putting them into the machine, it helps the hatch. They then warm up quicker, and as it takes time to collect enough to fill a machine where one only has a few hens, I conceived the idea that in this way some of the moisture taken away by evaporation, could be restored. Certain it is, that eggs treated in this way, produce better hatches for me so I pass it on for others to test.

I am anxious also to test a new little machine which is said to hatch every day as well as if the eggs were all put in at once. That is, one can save eggs from each hen and set them two days apart, thus toe-marking and pedigreeing the chicks by means of this new fangled contrivance. Sounds particularly good, if it proves out, but so many things claim to revolutionize the world, then fail to "make good." We can only try those which appear good to us, and judge by experience.

The Inglewood Poultry Colony is about to hold an unique exhibition in that utility, and not feathers and "points" are to be given prizes. I want my neighbor who has a hen which lays two eggs a day, (by spells) to exhibit the freak, but she is such a homely specimen, I don't know whether he will or not. The Hogan system is to be the test used to govern the awards. I have some hens which "test" finely under this system, but I am not saying that they are my best layers.

POULTRY QUERIES.

Rheumatism.

I have a Rhode Island pullet hatched last October which has some trouble with the cords in her feet, which seem to draw, so she stand on her toes, or else sits on her knees to eat. She seems perfectly well only for this trouble. She has only been troubled this way a short time. I have a Rhode Island Red rooster which has his legs enlarged from the knee down. They are rough and at feet seem to crack just as our hands would. I used sulphur and lard, but it did no good. He eats well and looks well only for this trouble.—R. H. Grimes, Colusa Co.

The pullet has undoubtedly been fed too concentrated food and not had enough exercise, which, combined with the damp weather has brought on rheumatism. Feed plenty of green feed and no meat of any kind, and especially give her celery tops if you can get them. A dose of Epsom salts will also be a good thing, and bathe her feet and shanks with some good liniment. Treat the male in the same way as to food, and plunge his legs into a pail of kerosene clear to his knees twice a day until the scales come off clean. Usually three or four days will affect a cure in stubborn cases. This is a very severe cure, but also very effectual in stubborn cases. Where his feet are cracked, a dressing of vaseline after the plunge bath would be helpful. Are you letting these birds run in the wet where ashes have been thrown? Is there alkali in the soil? Surrounding conditions have much to do with such troubles as you describe, and dampness will cause a whole train of troubles —Mrs. F. M.

GRIT FOR HENS.

With regard to the grit fed to hens I may say, that this opens a very interesting field. It has been said that the grit itself has only one function, and that it is not used for grinding food, and that it has absolutely nothing to do with the grinding process. I have been following the discussion quite closely, and I feel that the first thing we ought to do is to get some facts. I believe that the grit loosens up the grain in the crop, and helps to work the juices together, whether you call that grinding or not. Whether they get any mineral matter out of it is questionable.

I took twenty White Leghorn cockerels and divided them into four flocks and put them into separate pens and did not give any of them a bit of grit to eat for one week, but allowed them to eat grain and all they wanted of it. I fed them two or three times a day both on hard and soft feed, and at the end of that week took the first pen and gave them what grit they could eat, and they had all they wanted. The pen right opposite to them did not get any grit at all, but I waited until I saw what the first pen ate, and then put that much grit into a grinding mill and ground it just as fine as flour so that they would get all the mineral matter that was in it, but they did not get any grinding material. I fed that to that pen, and then to the next pen I gave neither the grit nor the meal nor the ground grit; I put off by themselves and gave them all the grit they could possibly eat and then took it away from them.

I kept that fourth pen just to die for their country, and at the end of three weeks killed one of them and took out the grit that was in the crop, washed it off clean and put it in a bottle and weighed it, and there was actually more grit in the bottle than the fowl had eaten at the end of the first week. The grit had been there before; gravel and stones and pieces of coal.

At the end of four or five weeks I killed another one and there was more grit left in the gizzard than the fowl had eaten at the time I filled it up, and I waited five or six weeks and I killed another, and there was still more grit in the gizzard than there was at the time I started to feed them. Some of these little pebbles were just as smooth and round as they could be, for they had been rolled over and over so many times.

So far as the actual results in the vitality and growth are concerned, the ones that had the grit by them all the time where they could help themselves had done better than the others; but the difference is not so marked as I thought it was going to be. There are some individuals in the pen that have not had grit nor the mineral matter ground up for them that are just as bright and husky as those that had the mineral matter and the grit.

You can learn more from pullets than you can from cockerels, so I put some late hatched Plymouth Rock pullets in one of these colony houses, and another bunch in a similar house and fed them the same way, except one of them had no grit all the while; and as yet I have not seen any marked difference as to their health or condition. I find that the hens are not laying many eggs; they eat about equal parts of the grit and cracked oyster shell, a little more oyster as a rule; and when they are laying rapidly they will eat two or three times as much, which would indicate to me that the hen naturally feels that she needs it.—Petaluma Poultry Journal.

Special Prices

Today we have on hand a few of the latest models of the "Old Trusty" Incubator, just as long as they last you can have them at the lowest prices ever made by any Incubator company in the West. We wish to get our money out of them quickly, we will hold any machine you wish to select if you send a $2 deposit, these machines will not last but a few days at these prices. Now is the time to BUY and save many dollars while you can. This ad may not appear again. If you do not have the catalogue. 148 pages, send for it. We pay R. R. freight in Cal. 120 Egg Size, $10.90, 165 Egg Size $12.90, 240 Egg Size $15.90. These machines are all complete with all attachments ready to run.

When the chicks are hatched don't feed them anything for 24 hours, then feed them the best dry Chick Feed you can get. We say that is

West Coast Chick Feed

Read what others say:

SAMUEL R. KELLAM, former president of the L. A. Co. Poultry Association, says: "West Coast Chick Feed is the best feed for young chicks I have ever used. I have given this feed a thorough test, and have always found that it produced fine, large, healthy chicks."

MRS. A. BASLEY, the celebrated poultry authority, says. "I want some more of your West Coast Chick Feed, for it is excellent. It is purer, cleaner and appears better balanced than other feed I had been using, and to tell the truth, I have been experimenting, feeding both together, and they always eat yours in preference."

Ask your neighbors, for there is more of "West Coast" sold in Southern California than all other kinds put together. If not sold by your dealer send us $3.50 and we will send a 100 lb. sack, freight prepaid within 300 miles.

PRICES FOR PURE-BRED POULTRY.

We do not hear so much now as formerly about the "Golden Mean," a phrase which originated, as the writer believes, with the Greeks. The present age has pretty nearly forgotten it.

Sometimes there is criticism of the high prices often paid for pure-bred poultry and for eggs for hatching. And the criticism is often justified. Too high prices are paid in many cases. But whether the price paid in any particular case is too high depends not only on the quality of the fowls or eggs purchased, but also upon other things.

We know of cases where as high as $1,000 has been paid for a single specimen of poultry. Was the price too high? Well, if the man who sold the bird could get $1,000, do you blame him for getting it? In such a case the price is not too high for the sellers point of view. And if the buyer wants the bird a thousand dollars' worth and has plenty of money with which to pay, then he must be the judge as to what price is too high. That price would be too high for the writer of this article to pay, that is certain, but I am not going to undertake to decide what some one else can afford to pay, or ought to pay. One thousand dollars is a big price to pay for a fowl, but is it any higher than $10,000 for a boar, $17,000 for a bull, or $44,000 for a cow? These prices have been paid in this country.

I suppose that no good business reason can be given for paying $1,000 for a single fowl, but often a breeder, particularly if he is in the business for a living, is justified in paying a good price, a big price, in fact, and he has a right to ask as big a price as he can get.

A breeder of Silver Wyandottes who had for several years been making his entire living from breeding this variety and selling his birds and eggs for a big price, showed several very fine females at the Madison Square Garden Poultry Show at New York, the greatest show in America. A rich man wanted to buy his three best females. The breeder refused to sell for various high prices offered him. Finally he said: "I can't afford to sell these pullets except at a price which will warrant me in retiring from this business. I am making my living out of it and a good deal more. I am known as the best breeder of Silver Wyandottes in the country. I have been years in building up my flock to the point which it has attained in my best birds you see in this show. If I sell them I am no longer at the top, and my business suffers." Now wasn't this man right? Didn't he talk good sense? And yet some would have said he was foolish for refusing $500 or any like sum for three "chickens." Maybe people were foolish for sending from all over the world to this man for Silver Wyandottes at fabulous prices, but the fact remains that they were doing it, and he surely would not be justified in throwing away a permanent, profitable business for a few hundred dollars.

This article, however, is not intended to urge any reader to pay "fancy" prices for pure-bred poultry, but it is written with the idea that some readers will see that if they desire to get really first-class pure-bred poultry they should expect to pay what is considered a fair price, and should be willing to do so. They should not expect, for instance, to buy first-class pure-bred fowls for $1. Nowadays the carcass of a fowl of good size is worth that. I killed a cockerel that at the time was worth over $1 at the meat market. And yet if I had asked some one a dollar and a half for this cockerel, including the labor and expense of boxing him up and delivering him at the express office, some people would have thought I had an immense amount of nerve. There would be no profit, and surely no satisfaction, in raising a bird like this and selling him at butcher's prices. I know a breeder of Mammoth Bronze turkeys who sold some fine big toms dressed at 20 cents per pound. For one of them he got $5 as he weighed 25 pounds dressed, and of course this is not an unusual weight for a male turkey, in fact it is under the Standard weight for a full grown tom. But this man told me that if he had quoted a price of $5 to some people for this bird for breeding purposes they would have fainted. But isn't a first-class bird for breeding purposes worth twice his value for eating purposes and up?

The value of a pure-bred fowl depends upon how good he is, and upon his breeding. Each person must decide for himself what he ought to pay. But one must expect to pay a reasonable price, a price at which the seller can make a fair profit, and from this price up if he buys something of the highest quality and buys from a breeder who has a wide reputation. Such a breeder charges for his reputation which has cost him years of time and much money to build up. And he has a right to charge for that reputation, and so will you when you arrive at the point at which he has arrived.—Kansas Farmer.

SELECTING LAYING STOCK.

There are a great many methods advertised in various pamphlets and papers stating that if you will practice this or that method of selecting as laid down in the paper you will be able to select the drones from the workers. The writer has tried some of these methods and knows the trap nest is the most accurate every time. It is by selection and keeping records that advancement is made along this line. Each hen has her own individuality. Certain hens lay eggs that are nearly always hatchable. Some hens lay well, their eggs are nearly always fertile, but will not hatch either under hens or in incubators. The chicks will develop to a certain size, often fully formed, but die in the shell. A few hens lay eggs that are seldom fertile.

In selecting birds one has several objects. The saying is often heard that "the hen that lays is the hen that pays." The majority of those in the business consider egg production the best end of the business. It is often the surest. There is less risk attached to it. If the production can be increased five to ten eggs a hen per year you are doing a good business. The writer is inclined to believe that the average hen does not produce over eighty eggs a year. At the Maine Station, where the trap nest system has been in use some years, the record last year was between 135 to 140 eggs per hen, which shows a considerable gain over previous years. Wonderful improvement may be made by selection for a few years, but after that progress is slow. There must be a good many conditions favorable to make advancement. It

is necessary to discard all hens that do not come up to a certain standard in egg production, and select males from the very best producers. Many people have claimed to have made advancement by selecting certain types of layers, but this is not always accurate. It has been found, however, that a female possessing a nice clean cut head with a full bright eye usually is a good producer, or in other words, hens showing feminine character and not those showing too much masculinity should be selected. A hen with a large crop has a better chance of being a good layer than one with a small crop. If their crops are examined at night considerable variation will be found. Dairymen know that a cow must have capacity to consume food in order to give a large quantity of milk.

One hundred pounds of dry poultry droppings contain elements of fertility that would cost good money if bought on the market.

WHY HENS LAY EGGS WITHOUT SHELLS.

There are several reasons for this, and while shell-less eggs are generally attributed to a lack of sufficient shell-forming material being supplied to the hens, in nine cases out of ten improper feeding is at the root of the mischief. This is demonstrated repeatedly by the fact that, even where shell-forming matter is supplied in abundance, hens will still lay shell-less eggs. In that case we must look further afield for the cause.

A great deal of mischief is done by feeding on over-stimulating foods and the reckless use of condiments which overexcite the ovary, and inflame the lining membranes of the oviduct. In this way the egg-producing organs are stimulated to excessive production with the result that the oviduct becomes diseased and those organs which produce the mineral matter for the shelling of the egg are too debilitated to perform their function properly. It is worthy of note that fowls suffering from inflammation of the oviduct often lose the use of their legs, the trouble being frequently attributed to cramp.

A very common cause of shell-less eggs is internal fat, which blocks the walls of the oviduct and impairs its functions. Worms in the hen's intestines sometimes lead to eggs being expelled before they are properly shelled. Narrow perches are also responsible for shell-less eggs, the eggs being dropped prematurely, owing to the struggle of the fowls to retain their balance. Similarly, fright will cause a fowl—more especially a pullet—to expel the egg before it is ready.

When a fowl has acquired the habit of laying shell-less eggs there should be a complete change of diet. All soft food, except what is cooked, or juicy vegetables, which may be freely supplied, should be withheld for a time and grain only be given. Enough Epsom salts should be added to the drinking water to make it taste faintly saline, and for a few days the fowl should be housed in a quiet place. To help steer clear of shell-less eggs always supply the fowl with plenty of flint grit and guard against internal fat by feeding moderately—two meals a day are ample—giving a plentiful supply of green stuff. Perches must be of the proper size, and, above all, leave condiments and all that sort of thing severely alone.—W. R. Gilbert, Portland Oregonian.

MAY BE?

In a statement to the French Academy of Sciences, an observer says he has discovered a sure and easy means of telling whether an egg will produce a male or a female. His view is that "eggs containing male germs are wrinkled at the small end, while those containing female germs are smooth at both ends."—Ex.

A little bone meal added to the chickens' feed will prevent bowel trouble and weak legs.

Arrange the nests so the fowls can't roost on them. A board on top will do it.

Six square feet of room per bird in the house and 100 in the yard will be about right.

The creamery at Benicia will soon install a 20-ton refrigerating machine.

BUY CHICKS NOW! DON'T WAIT!

We can sell you baby chicks right now as low in price as when eggs are much cheaper. We can ship safely anywhere within 48 hours. **WE HATCH** 19 varieties of poultry. Send today for price list; it gives full details how we sell and ship chicks, etc. We have satisfied customers everywhere. We guarantee you a square deal. Frank E. Baldwin The White Leghorn Specialist

46 Washington Avenue, San Jose, Cal.

February 6, 1909.

Dear Sirs:—

I have used your Poultry Tonic for a long time and think there is none so good. But you have one remedy, POLLY OIL, I do not feel you know its worth. I had one little sample bottle given me a few weeks ago. I used it on two cases of swell head and it stopped the swelling right away. I had one pullet on which the lump had stayed for over two months, her bill having grown crooked, but as she was a pet I could not have her killed, but could not drive the lump away until I got the sample of Polly Oil. It then commenced to go away, and in a few days is was nearly gone. I have cured every one since that showed any signs of such trouble. I have used all I have and do not want to be without it.

Very respectfully,

FANNIE L. E. WEBBER, Pasadena, Cal.

If not sold by your dealer send the price, 50 cents, and we will send you a bottle, prepaid. WEST COAST MILL, Los Angeles, Cal.

The Ukiah Times appeals for a crusade for better farming.

Farmers' Educational and Co-Operative Union

The attention being attracted by the great Farmers Union movement makes it worthy more extended notice. We are glad to have the following from the pen of P. F. Adelsbach of Kingsburg, who is a deputy state organizer in this work. The movement is having large increase in the raisin section.

IN all the history of organizations for farmers, there has never yet been one that attained the phenomenal growth of the Farmers Union. This organization is less than six years old, yet it has already a membership of 3,000,000 and is gaining steadily each week and month.

It was at Point, Raines county, Texas, that Newt. Gresham founded the first Local of the Farmers Educational and Co-operative Union of America, for that is the name of the organization concerning which we are writing. Because the cotton market was very bad and the prices received for the product were below the cost of production, it was deemed necessary to have some sort of organization among the cotton farmers, and the result is the Farmers Union, as we know it today.

In the South, the cotton industry has received a new life, so far as the producer is concerned, for he now receives, in nearly every instance, a price that justifies him in continuing the cultivation of that staple, a condition that did not prevail before the producers, through the Union, got together and sent a consignment of their cotton direct to the spinners in Manchester, England. The result of the experiment was that the growers received 12½ cents for the product instead of seven cents, as before from cotton speculators.

Hang Together.

While the Farmers Union was born and has had its greatest growth in the South, it knows no South, no North, no East, no West—it goes wherever the farmers are, for all farmers need the organization. All other lines of industry find themselves organized, but the farmer class has been slow to come into the fold. There is an old saw that "Men must hang together or hang singly." The Farmers Union has all the good features of the organizations that have gone before, with a great many new ones added; and the features in the old that proved stumbling blocks in the way have been left out of this.

Politics and religion are forbidden discussion in the hall where the Local holds its meeting. Only the purposes of the Union, ways, means, objects, etc., are to be dealt with in a meeting and the plan of going into politics to achieve an end is absolutely forbidden. The Union is a secret order, with its signs, pass-words, grips, etc. This makes it possible to keep out those who are not desirable as members, and gives it a dignity and tone much to be admired. Some have offered objection to the Union because of the secret feature, but there is no reason for complaint here. It is secret only in the sense that its business and affairs are to be kept from those who should not know the inside workings of those who have combined to plan, in a legitimate way, against certain conditions which make farming sometimes unprofitable. It is secret only in the sense that the affairs of a firm are kept secret, or that family matters are secret. Persons holding religious scruples against secret orders, will find in the Union, if they investigate, a sort of secret society they can well admire, for the man or woman who lives up to the teachings of this institution will indeed earn a large reward from Him who sits on the Throne before which all men come.

Who.

Any white person, over the age of sixteen years, male or female, of industrious habits, who believes in a Supreme Being and is of good, moral character, who is a farmer, farm laborer, rural mechanic, school teacher, preacher, physician, and who is not engaged in banking, merchandising, practising law, or belonging to any trust for the purpose of speculating in agricultural products, provided the owning of bank stock by an actual farmer shall not be construed as making him a banker so long as his principal income is from the farm, and newspaper men, by taking a special obligation, may become members of the Farmers Union.

A fee of \$2.00 is required upon joining, and national dues are 15 cents per quarter. In addition to this, the local dues are such as may be fixed by the Local, each for itself. Women in no case pay fees or dues. Officers are elected in the usual manner, but at any time, if one should prove not worthy of the trust placed in him, he may be recalled. The right of initiative and referendum is one of the principals practiced by the Union. Local Unions may be chartered with not less than five members, but never yet has one been organized with so small a number. Cases are common where the charter list contains from 100 to 200 members.

Stayers.

In California the Union first took root at Kingsburg, Fresno county, something like three years ago. It was a hard, long fight, and those who were the first to see the value of the Union and to form their Local were persistent in their staying qualities, or perhaps the Union would ere this have faded from California, rather than, as is the case today, making the most remarkable growth of anything of its kind ever known.

State Organizer.

Last November the National Executive Board, in answer to the call of the few pioneers in Kingsburg, sent as State Organizer for California, Hon. W. W. Welch, of Mississippi, who has made his home and established state headquarters in Kingsburg. Prior to his coming to this state Mr. Welch was the State Business Agent for the State Union of Mississippi, and gave up that position only because the poor health of his wife (who passed to her reward only a few days ago) demanded a change of climate. Her physician recommended that she come to California. Hence the presence of our State Organizer, who has done wonders in the way of waking up an interest that makes it possible for the Union to spread like wildfire.

In less than three months, more than 2,000 members have joined the Union in three counties: Fresno, Kings and Tulare. There are now close to 3,000 members in the state.

Markets Are Not Stable.

One of the chief reasons given for the wonderful growth of the Union in California lies in the fact that the late crop of peaches and raisins is being "held over" by the growers, with no prospect of getting even enough out of them to pay the cost of production. This caused the growers to look to the Union as a possible way of escape. The raisin market has been played with by the packers until it is so very unsteady that many Eastern buyers will not invest in California fruit and raisins for the reason that they do not know how prices will be within the next 24 hours. The stability of prices on our kinds of fruit, was and is utterly destroyed. The Farmers Union, in this case, proposes to establish the prices at a point where it will be profitable for the growers and at the same time encourage the retail dealers in the East and Middle West to stock up more freely.

Why.

It is freely asserted that in many of the larger cities in the East the retail stores carry very little if any California dried fruit and raisins. The reason is set forth above. There is no reason, if the market is properly handled, why the entire crop, now a drug on the market so far as the growers are concerned, should not be unloaded on an open and ready market. Letters have been received from people in several Eastern states, asking what was the matter with the California raisin crop—was there a failure or what was it? The inquiring ones were unable to buy raisins at any price at their retail stores, hence the query.

Not So Small.

It is the purpose of the Farmers Union to take hold of the problem at this time. The Union owns and controls more than 5,000 warehouses in the South and Middle West. The plan is to ship, as a starter, 10,000 tons to the several warehouses in the larger cities, and then to send agents out to dispose of the product to retailers, and if the retailers will not buy, then to the consumer direct. Some investigation has been made along this line, and it is believed the scheme can be carried to a satisfactory conclusion. The tricks of the speculators are many when it comes to causing delays and annoyances to those who would market their own product, thereby ignoring the middleman and the broker, but there are those in the Farmers Union who are "wise" to all these and while some annoyances are expected in connection with the present scheme, it has been resolved to stay with the ship until victory shall crown their efforts. The Farmers Union label is to be used on all shipments, and all goods are to be packed under it. It is calculated that this will be of material assistance in getting the goods through, for all Union men are to be appealed to to assist in the work of bringing Union goods to the front.

Federated Warehouses.

Under a plan recently adopted all the warehouses of the Union in the United States are to be federated. This will mean a wonderful advantage to all Union members. Under that scheme it will be possible for a member to deposit his product in the

DEAD CITRUS WOOD

Is more or less prevalent in every orange and lemon grove, i. e., trees that are unprofitable. How many such have you in your orchard? Would it not pay you to put paying trees in their stead?

Your Home Grounds

Should contain at least a few trees of the better varieties of oranges and lemons. For this purpose we have some exceptionally fine trees to offer, being grown as specimens. Possibly you would like to plant a few citrus trees about your home this season. If so, will you do us the favor to correspond with us about it?

Citrus Fruits

Historically, Horticulturally, Commercially.

Our new booklet gives more valuable information about varieties, methods of planting, cultivating, pruning, picking, packing and shipping than anything of its kind ever issued. Sent anywhere for the small sum of 25 cents. Correspondence a pleasure.

Union warehouse, and if his bank will guarantee the quality of his goods, he will be able to draw three-fourths of the market value at once, the balance to be paid him upon the sale of the goods. These warehouses are to be under the management of a Board of Control of three men, each of whom is to be under $10,000 bonds. The money is in no case to pass through their hands, but all financial matters will pass through the bank indicated by the man who deposits his products in the Union warehouse. This plan has been some time in working out, but the national officers feel that the time has come when they will be able to carry it out, and within a very short time, it is expected that announcement will be made that the federated-warehouse is ready for business.

Hope of the Farmers.

In Central California nothing is receiving the attention that has been attracted to this movement. The hope of the farmers and the salvation of the country seems to be within the Union, and at the rate of increase in membership being experienced, it would seem that it shall not be long until the day of redemption for the farmer is at hand.—O. F. Adelsbach, Kingsburg.

An Agricultural High School

We are pleased to give the following statement of an effort which we trust foreshadows many similar ones in this state. It is written by Mr. Mark R. Jacobs, principal of the Gardena High School, which is under the control of the Los Angeles School Board, and is among the first efforts of the kind in the public schools of the state.

IN REPLY to your inquiry relating to the study of agriculture in the Gardena High School, I wish to state that as yet we have done little more than to formulate in a general way the plan we propose to follow. A high school education, as a rule, points the young man to the city as the most promising place to establish his life occupation. We propose to combat this idea, or at least to educate our students in such a manner that those whose lot it is to till the soil may find their work more pleasurable through having infused into it an intellectual and esthetic element. Is it really quixotic to assert that the day is not far distant when farming shall be classed along with the professions?

During the past term our students have done a considerable amount of practical work which they entered into with zest and performed apparently with a great deal of pleasure. They drew up plans for beautifying the school grounds, laid out walks and set out trees about the school, and this week have just finished putting in a half-acre lawn in front of the school building.—Mark R. Jacobs, Gardena.

The Gardena High School at present, has about three and a half acres of land, part of which is under cultivation. During the coming year the Board of Education of the city of Los Angeles will spend twenty thousand dollars in acquiring more land and equipping laboratories. General Science, a laboratory course treating principally of the fundamentals of plant life, is being given as a ninth grade study this year for the first time. This will lead up to agricultural botany in the second year, inorganic chemistry and the chemistry of foods in the third year, and physics and farm mechanics in the fourth. With these subjects, out-of-door work will be given whenever practicable. Next year we hope to introduce carpentry, domestic science, and poultry raising in a small way. Along with these we shall offer the usual culture subjects such as English, history, mathematics, music, drawing, etc., believing that the combination of the practical along with the disciplinary and esthetic subjects will result in a course of study better suited to the needs of the high school student than is ordinarily given.

EGYPTIAN COTTON IN COACHELLA VALLEY.

Of my two small plantings of Egyptian cotton, one was five weeks late and the other eight weeks late. I take the first of March as the most suitable time to plant. It did not mature all the bolls but it made a firm growth. I have picked different stalks that produced three-fourths of a pound of seed cotton, with enough undeveloped bolls to make it a full pound. As there would be something like 3,000 plants to an acre, and giving each plant the proper distance, it can be seen that it would produce about 3,000 pounds an acre, making two 500 pound bales of lint cotton. If the crop will average even one bale an acre, we have a good paying crop; one that, moreover, requires but little water, no irrigation after the first of September, and but two to three cultivations. It is planted about the first of March. It requires about five pounds of seed an acre if planted by hand, and about 15 or 20 pounds if planted by planter. Make the rows 4½ feet apart and plant two feet apart in the rows. Irrigate before planting, but do not irrigate after planting until the plants are up, as the seed rots very easily.

Why not make the semi-arid Southwest a cotton-growing country, with a cotton factory at Los Angeles, and this valley and the Imperial and Palo Verde country to grow the cotton? We have ideal conditions to produce a staple crop.—A. W. McGill, Thermal.

Bees and Their Care

BEES AID THE GROWERS.

"GIVE THE bee a chance and it will literally break the boughs of your trees with the weight of fruit."

Frank G. Odell of Lincoln, Neb., bee-master, who gave a series of demonstrations with 50,000 bees at the National Apple Show in Spokane, in December, made the foregoing observation in the course of an interview, discussing bee-keeping, scientific agriculture and fruit growing. He said:

Expert Assistant.

"The bee is the expert assistant of the horticulturist and the farmer. So indispensable are its functions in the pollination of fruits, vegetables, cereals and grasses that its activities may be said to lie at the foundation of all successful agriculture. Nature has ordained one supreme law, that of creation, the perpetuation of the race type. This law, universal in its application and absolutely identical in its form, obtains in the plant world as in the animal world. The luscious pulp of the fruit is the envelope, the package, the strong box, devised by nature to protect the seed within from injury and render it susceptible of germination so that the type may be reproduced in all its perfection.

Aids Pollination.

"The bee, like other insects, effects incidental pollination of flowers in its search for nectar; but its great value to the fruit grower lies in this, that it goes to the flowers specifically to gather pollen, literally by the carload, in the hairy baskets on its legs, hastening from bloom to bloom, rolling and packing and literally rioting in the golden dust, pregnant with the microscopic germs of plant life, until the golden pellets are packed away in its hair baskets, to be carried to the hive for storage as an indispensable portion of the food of its young during the winter months to come.

"It requires no expert knowledge to comprehend how perfectly the bee thus performs the office of pollination. Indeed, it is nature's chief agent in this indispensable work. No seed, no fruit, is the universal law. Here is the only insect useful in all its habits, having a fixed habitation accessible to man, dependent upon the pollen of every variety of flower as an indispensable portion of the food of its young, and going to the bloom specifically to gather that pollen, thus making possible the marvelous fruit crops in Washington and the Pacific Northwest. That is why I say, give the bee a chance and it will literally break the boughs of your trees with the weight of fruit.

"Delve into the realm of applied mechanics or structural engineering and your research is incomplete until a lesson is conned from the structure of the honeycomb with its marvelous strength as compared with the fragile nature of its fabric. No more marvelous structure exists among the myriad marvelous works of nature. This waxen fabric, derived primarily from liquid honey converted into wax in that marvelous laboratory of the bee, formed by some mysterious instinct or intelligence into the very form of all others designed for economy of materials, space and extremity of strength, passes beyond the measure of human skill in its perfection.

How Wax is Made.

"Somewhere between 1744 and 1768 it was discovered that wax is produced between the plates on the lower side of the worker bee's abdomen. It was John Hunter, the celebrated anatomist, who discovered just how the bees secrete wax, and thereby settled a vexed question. He communicated his discovery in a paper read to the Royal Society of London, February 23, 1793.

"Wax is produced at the will of the bee, and when called for by the necessity of the hive. The wax-producing bees obtain a somewhat higher temperature, usually by close clustering, though they sometimes hang in slender festoons and chains.

"Wax is not chemically a fat or glyceride, and those who have called it 'the fat of bees' have grossly erred; yet it is nearly allied to the fats in atomic constitution, and the physiological conditions favoring the formation of one are curiously similar to those aiding in the production of the other. We put our poultry up to fat in confinement, with part light; to secure bodily inactivity we keep warm and feed highly. Our bees, under nature's teaching, put themselves up to yield wax under conditions so parallel that the suitability of the fattening coop is vindicated.

"Chesire in his investigations says that on the inner side of the eight plates lining the lower side of the abdomen are about 140,000 glands, from which the wax is secreted as a white liquid, which hardens on exposure to the air.

"It is evident from the best authorities that the form and method of wax secretion were known as early as 1691, and possibly at even an earlier date. The extraordinary economy of the use of wax is shown by the fact that the hive of 8 to 10 gallons capacity will yield but about two pounds of wax when melted. According to Dr. Denhoff the thickness of the sides of a cell in a new comb is only the 1-130th part of an inch. Chesire states that he found some that measured only 1-400th part of an inch.

Beats Us.

"Nothwithstanding the fragile nature of the honeycomb it is still sufficiently strong to carry the relatively immense load of sweets stored in its cells. The perfection of insect labor is shown by the fact that human ingenuity has never been able to make artificial honey-comb. The tales concerning manufactured comb honey are figments of the imagination. Consider that any machinery devised for manufacturing honeycomb would make all parts alike in similar sections. Examine carefully two or more one-pound boxes of honey at your groceries and you will note differences in the finish of cappings and building the comb fast to the wooden casing, which at once convince you of the genuineness of the article.

"Not only does the bee excel as an artisan, but also as a chemist. Its honey stomach is the most delicate chemical laboratory in the world. Here the nectar of the flowers is transformed from a highly diluted sweet, susceptible of speedy fermentation, into the most perfect food product known. This chemical change, inverting the sugar, according to the chemist's phrase, is undoubtedly accomplished in the laboratory of the bee during its short flight from the field to the hive. This chemical reaction is so delicate that no laboratory aside from that of the bee can successfully accomplish it.

Monarch of All.

"Consider the Queen bee, the sole and undisputed monarch of her empire. Endowed with powers superhuman, she governs without exercising visible authority, rules without coercion. Her subjects go about their tasks with that cheerful zeal which can only accompany toil fully recompensed, and offer to men, torn into factions of contending opinion, an ideal social state, where every member of the community is a toiler and all are prosperous, peaceful and content.

"The queen bee is sole mother of the race. 'All life from the egg,' that great biological axiom, is exemplified in the hive. The queen mother passing rapidly from comb to comb, places a single egg in each selected cell, laying the inconceivable number of 3,000 to 4,000 in 24 hours. This labor represents in a single day the expenditure of physical substance equal to two and one-half times the weight of her body. Consequently she does not even feed herself, being always accompanied by a devoted group of maids of honor, worker bees, whose office it is to bring in profusion the choicest predigested food to their ruler. Not the least of the wonderful powers of the queen is that of predetermining the sex of the offspring which shall result from eggs precisely alike under the microscope, but which, in turn, may eventuate in a worker, drone or queen, as their mother may elect."

It is well to keep an eye on robber bees, especially, when there is a let up in the flow, but the exercise of care in this respect will prevent any serious trouble.

MORE LAWS FOR BEE-KEEPERS.

The machinery has been started in California to give the apicultural industry some legislation that will set the old don't-care-a-rap fellows to thinking. The present foul-brood statute is to be amended, provided the work Mr. Ralph Benton, of the State University, has been formulating succeeds in meeting the approval of the Solons now assembled at Sacramento. Mr. Benton is aiming to place the inspection of infested apiaries more under the control of the authorities of the State University, at the same time allowing the appointment of county foul-brood inspectors to remain in the hands of the supervisors of the several counties as at present. It will be more binding on the supervisors to make appointments when petitioned to do so. The University Inspector of Foul Brood will have co-extensive authority with the county officer, and he will have power to appoint deputies to assist in the work. This will allow of scientific investigation; at present it is said some of the inspectors are ignorant of what a genuine case of foul brood is like, as is so often the case when politics has a hand in the filling of scientific positions. The amended law will weed out poor or bad inspectors.

There is one thing about the amended statute, as drafted by Mr. Benton, I do not think should be put in force for some years to come, and that is the provision making it compulsory for all queens and their attendant bees passing inspection by the foul-brood inspector; in fact, they must be accompanied with the certificate of inspection, as are consignments of trees and plants, before they can enter this state; and if not so certified they must be placed in a hive for sixty days, and be subject at the expiration of that period to final inspection by the officer. If no sign of foul brood or other disease inimical to the best interests of California beekeepers has manifested itself, then the bees and queens will be admitted.

My objection to this is that, owing to the fact that as many Eastern states have no properly constituted officer who could give a queen-breeder a clean bill of health for his bees and queens, it would be a hardship on a reputable breeder to hold his bees up on that score. Then I believe it would be an injury to a bee-keeper and the exporter as well to have bees held up at the post office or express office until some far-away inspector could be brought upon the scene to poke the poor bees in the ribs and look down their throats to see what they had for breakfast, or to find how their alimentary system was. Mr. Benton agreed with me that, while the provision would ultimately be beneficial to our bee-keepers, it was better to wait a few years until a like law was enacted in the Eastern states where bee-keepers raise queens, before this provision should be in full force and effect. So I believe he will have the proposed law so changed.

Then he makes provision for an annual meeting of foul-brood inspectors. This is good; but I am afraid the interest will die out in a few years. By making such meeting a part of the annual meeting of the State Bee-keepers' Association it will provoke more interest and be far more beneficial. In fact, I believe it will bring about a greater attendance at such meetings. The new law, if passed, will allow for the printing of the report of proceedings of inspectors' conventions —a good thing in itself, but it would also be good, and perhaps better, as I suggested at the Monterey meeting, if the State would make provision for the printing of the proceedings of the State Bee-keepers' Association. Such aid is already given the horticulturists, viticulturists, mining interests, I believe, and the horse-racing outfit —the latter a useless waste of the people's money.

In order to carry on the work to be placed in the hands of the University pathologist, an appropriation of $2,500 is asked. This sum is modest compared with some appropriations that are demanded from the public treasury; but, taken in connection with the salaries of the various county inspectors, the amount to be paid for stamping out foul brood will be considerable. Yet as the honey industry is no small one in this state, and materially adds to our prosperity, we can well afford all that it costs. There are thousands of leaks that, if stopped, would allow beneficial enactments to be made for many purposes. I mention this for the reason that I have always been opposed to piling new laws into our statutes and making needless appropriations for this, that, and the other thing, to burden a long-suffering tax-burdened people. But the bee-keepers have never asked much; they now seek an intelligent means of overcoming an evil that has long embarrassed them. The proposed law is worth trying. May it be passed; and should it prove ineffectual it can be changed.—W. A. Pryor of Oakland, in Gleanings in Bee Culture.

The editor of Gleanings adds: "As a matter of fact, we do not see how the inspector, no matter how competent he may be, can determine whether a queen with her attendants in a cage has disease germs in her alimentary canal. Nothing but dissection would show this, and this, of course, means the killing of the queen. Even if the inspector were disposed to allow the passage of such queens, the delay in the postoffice until such inspection could be made would very probably result in the death of the queens especially in the inaccessible mountain districts.

Some years ago we conducted a series of experiments, taking queens from foul-broody colonies and putting them in healthy ones. In no single instance was foul brood transmitted in that manner. We seriously question whether it is possible to carry disease through a queen, especially after she has been placed in a new environment on new food for a period of several days. Indeed, the McEvoy treatment itself, which is now recognized as a standard cure, applies no treatment to either bees or queens other than to remove them from their honey and combs and give them new food. That is precisely what the queen-breeder does when he picks up a queen and a few attendants and puts her in a mailing cage. Hence it follows that, if the queen should be taken out of a diseased colony, and sent through the mails, such queen could not carry the disease. In any event, no reputable queen-breeder would think of taking a queen from an infected colony and sending her to a customer.

We see no good reason, therefore, why queen bees and their attendants in an ordinary mailing cage should be inspected before delivery to the consignee."

The Seed House OF THE Great Southwest

Just received, one carload of **Eastern-grown Seed Corn,** and our **Colorado-grown Cantaloupe seed.** We have three strains, the **Eden Gem, Netted Rock,** and **Solid Net.** All of these have been tried, and proved more satisfactory than any other strains of the **Rocky Ford.** Dealers and Associations are requested to write for special prices.

Our carload of **Corn** consists of the several varieties best suited to the different sections of the Southwest. See page 112 of our catalog for description, and write for prices on large quantities.

WE INTRODUCE

Crimson Winter Rhubarb

Into New York and Philadelphia, and other Eastern Markets. Let us tell you more about our methods of introducing California Products under a Guaranteed Label.

We understand eastern conditions, eastern markets, eastern people, their likes and dislikes.

How to put up shipments in an attractive manner. We do not dump our goods on the Eastern Commission Houses and take a chance on getting a price. No! We go right out and create a demand among the high grade dealers under a special brand, and That Brand is a Guarantee that the goods are special first class. Our men are working among the Eastern Trade all the time.

EVERY GROWER AND SHIPPER

No matter what their present arrangement may be, should write us for information, for by our plan you receive the best prices paid in the Eastern Markets.

THE PHALANX COMPANY

513 Chamber of Commerce Building

Los Angeles, Cal.

Eastern Offices, Philadelphia and New York. Members of Los Angeles Chamber of Commerce.

EUCALYPTUS TREES

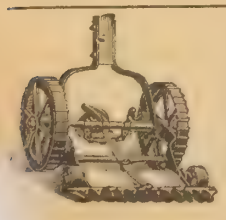
Large Assortment. All Varieties.

MONTEREY CYPRESS

Transplanted in flats 100 each. Write for prices, giving amount wanted.

W. A. REINHOLDLT

Main Street Nursery, Petaluma, Cal.



THE CLIPPER

Will cut tall grass and weeds and do all the trimming along the walks and drives. Your dealer should have them—if he has not drop us a line and we will send circulars and prices.

Clipper Lawn Mower
Dixon, Illinois.

Queries and Replies

Questions to be answered in this department should be received at this office one week before reply is expected. Write plainly on one side of the paper and sign full name and address. Unsigned communications receive no attention.

Olive Cuttings.

Will cuttings grow fruit true to the tree from which they are taken? How long before trees grown from such cuttings will bear? What are the most prolific bearers which at the same time yield the choicest fruit? Is the Mission a free stone? When is the proper time to gather for pickles.—M. M.

The olive tree is propagated in two ways, the nursery men using the tip cuttings of four to six inches long and rooting them on beds with bottom heat. The rancher grows them from ten to fourteen inch cuttings. They are calloused in the ground or sand then set into nursery rows and grown as fast as possible. About half will be ready for the next years transplanting. The remainder will be ready the second year to go out into the orchard. The most of a ripe Mission or any of the commonly grown varieties of olives separate from the pit when the berry is fully ripe. When the pit can be squeezed out they are "free stones." Most people prefer the ripe olive. The green is the better keeper, however. Cuttings will always come true to the parent tree.

Fox Terrier.

I have a thoroughbred fox terrier which is troubled quite badly with worms. I have tried different kinds of vermifuge, but it doesn't seem to rid her of them. I have also quit feeding her anything that is sweet. She is about a year old now.

Your paper is undoubtedly the best home, farm and orchard paper printed. —E. G. L.

Give her an enema of strong salt solution, little danger from being too strong. Use warm and with a fountain syringe all that she can possibly retain. Repeat second day and again in a week and again if you ever think it is necessary. The variety of food has little or nothing to do with it.

Contracted Hoof.

I have a colt, 9 months old, which developed a few months after its birth, what I think is contracted hoofs, on both forefeet.—J. H. I.

Your description does not make the condition very clear, but I should judge from your drawing that she walks up on the end of her toe; if so I should suspect that there is an anchylostomiasis of the lowest joint which makes a condition similar to a ringbone.

The tendon on the back of the leg may be contracted (shortened) which tips her up on the end of her toe.

You had better make a closer examination and report later, as it may have to have a surgical operation.

Oleander Scale.

The insect on the magnolia leaf received from a subscriber at Irwindale is the oleander scale, Aspidiotus hederae. Fumigation, of course, would be the most satisfactory treatment for this scale. As to the dosage which the magnolia foliage will stand, will say that I am of the opinion that there would be no danger in using even a stronger dosage than is used on the citrus trees. In case the trees are very large or if it is more convenient for the owner to spray, I would suggest spraying with 3 per cent distillate.—H. J. Quayle, Entomologist, Plant Disease Laboratory, Whittier.

Vinegar from Grape Juice.

The Cultivator recently had query as to making vinegar from bottled grape juice. The query was referred to the chemistry department of the State University which answers as follows by Hans C. Holm, assistant in zymological technology:

"In order to change grape juice into vinegar it is necessary to ferment it as completely as possible. This may be accomplished by adding strongly fermenting grape-must to the juice. When the fermentation has come to a standstill the fermented juice should be inoculated with vinegar bacteria.

"In order to prepare a starter of these bacteria proceed as follows: Take one-half pint of a good wine. Dilute it with about one-third this quantity of boiled water. Place it in a flat porcelain dish, and cover with a plate to keep out the light, in such a way as to allow free access of air. Place the dish containing the diluted wine at an even temperature of about 18 degrees, centegrade, (64 degrees Fahrenheit.

"In two to three days the surface of the liquid will be covered with a film of the vinegar bacteria and it will have a pleasant, strong smell of vinegar. Sufficient starter for the inoculation of about 200 liters (50 gallons) of wine will be obtained in this way. The starter should be added to the wine, which is placed in puncheons. The bungholes are left open, and the puncheons filled to about two-thirds of their capacity. If the wine is kept at a moderately warm and even temperature the vinegar will be ready in from two to three months. If the temperature is cold and uneven it will take longer."

Small Supply of Milk.

I have a fine milk goat fresh a month ago, that was in her third year when bred for the first time. She brought a single kid, small and feeble, which she carried 157 days—ten days longer than some of my goats. It was not till within twenty-four hours of his birth that she showed she was certainly making bag. We could not be sure of her condiiton. She has very large teats and a good type of bag, but gives only 1½ pints of milk instead of several quarts. The milk is very rich.. Can you tell me whether she has a fair chance to prove a good milker the next time she comes in? She is a large goat, but eats very little at present. Would the exhausted condition of the sire at breeding (for it was accidental, at a wrong time) be responsible in any way for the disappointing results?

Her younger sister, the fat goat about whose reduction Mrs. Sherman advised so well last fall, is now the anxious mother of a strapping pair of kids; and though she eats enormously they keep her thin.—A. R.

While I have never handled goats, I have had sows, cows and mares. Now theoretically we should breed better animals by not breeding the dams too young, yet when we do not

W... and if it was a cow that had been
U... accidently bred I should have given
her a drench of epsom or glauber salts as soon as I found she was coming in, to help relaxation. I think she will come all right if she is helped along a little. I should give her a physic at once and follow it with feeding of moist bran and after the second day add a handful of oil cake meal twice a day to her feed until she begins to eat well. Then gradually put her off on the regular feed tioned... the rest of the goats. It may be sp...more convenient for you to buy a few pounds of one of the standard brands of stock feeds. These will answer, as the oil meal is their helpful part put up with some aromatics that the animals like to eat. I am glad to hear the other goat came out all right and I think this one will do the same.—M. E. S.

Fig Cuttings.

Is it advisable to plant fig trees (Calimyrna) grown from young trees or from nursery cuttings?—M. A., Reedley.

If one desires to secure trees as rapidly as possible, fine trees may be grown from small branches even from nursery trees. However, where one can secure sucker wood from larger trees, it is quicker to root and quicker to give a large tree. Some even use only a single bud cutting.

Galled Shoulders.

Please tell me through your paper, what I can use to prevent galling of my horse's shoulders. I have tried gall remedies, I cut holes in the pad, changed collars, even turned her out on pasture until shoulders were well, but they seem to irritate and begin bleeding the first day's work.—Subscriber, Calabasas.

The best remedy we ever saw for the tender shoulders is a perfectly fitting collar without pad. Stick to your harness maker until he gives a good collar which fits the shoulders at every point. We have used all kinds of pads, and there are some horses on which they seem to work better than the collar alone, but as a rule, the perfect fitting collar is sufficient. Then wash the shoulders with cold water immediately on finishing the work; even at noon we have found that where the shoulders are tender it is well to throw off the harness and dash cold water, thoroughly drenching and washing out all the perspiration. Wipe lightly with cloth and have shoulders dried before the collar is put on after luncheon. At night wash with salt water, or some prefer strong alum solution.

White China Geese.

Several subscribers have written asking information regarding where White China geese may be secured.

Any subscriber who keeps them or knows of their being kept in this state, will confer a favor by writing this office.

Alfalfa Seed.

How much alfalfa seed is required to plant one acre of ground on adobe soil?—J. M., Stockton.

Twenty-five pounds will give you a good stand.

Drying Figs.

What preparation is necessary for the successful drying of the common fig? I have tried several times and failed.—Subscriber, Claremont.

You do not say what the trouble is with those which you have tried. The ordinary method consists in taking them as they drop thoroughly ripe from the tree and drying on trays in the sun. Once they are dried they are taken before packing in cartons and passed through boiling solution of salt which softens and destroys any insect alive which may be infesting them. It is possible your figs may have soured on the tree before being ready for drying. Some varieties are very persistent in this fault.

Grape Fruit Stock.

I have 2000 grape fruit trees a year and a half old. Half of them were budded to Valencias last fall, and I have just cut the tops off six inches above the buds. They have started nicely. When shall I bud the other half? That is, what is the earliest time possible?—E. A. B., Anaheim.

The spring buds may be set just as soon as the sap is flowing freely enough so that the bark will slip freely. It is possible on strong growing trees, this may be done at once. This you will determine by a trial. The fact that the other trees are growing nicely and have already sent out three inches of young growth, would indicate that the soil is warming up so that budding may be done at once.

Eucalyptus in Poor Condition.

What is the matter with my scarlet Eucalyptus? Was set in park way three years ago, water stood on lawn close to it a good deal during the

FARM LANDS FOR SALE.

L. W. JEFFERSON REALTY CO., 350 Market St., S. F., reports following sales of Alfalfa Lands, known as Hickman Land, at head of the Famous Turlock Irrigation District: W. G. McCutcheon, Coalinga, Cal., 40 acres, Julia E. Clark, of Nebraska, 45 acres. This lady and her husband only took fifteen minutes to decide after applying a ten foot auger and failing to find any hardpan. Prof. T. F. McConnell, of the University of Wyoming, agricultural department, 40 acres; Carl Pullman, of Oakland, 40 acres; Marion Gard, of San Jose, 20 acres; John Gibbs and Jas. Christie, of Knowles, Madera County, each 20 acres; Edgar R. King, Laramie, Wyo., 20 acres. The town of Hughson on the Santa Fe is to have a new depot built at once. Flack and Jacobs of Stockton, who opened up the Hughson tract of 2030 acres, sold it all inside of ten months. They have built a sixteen room hotel. The town supports a newspaper. The ladies improvement club are planting trees on all the streets. These people recognize the head of the Turlock Irrigation District as being the best place for alfalfa, oranges, lemons, and grape fruit, and the fact that the locality is free from malaria, overflow and water log, is attracting farmers, who are buying up all the good valley land under irrigation. For further information, free booklet, maps, etc., write to J. W. JEFFERSON REALTY CO., 350 Market St., San Francisco.

HALF RATES FOR MARCH—FOR only 25 cents an acre and our expenses, I will locate you on good government land, rolling, rich soil, fine pasture, about 8 miles off good railroad oil town, or on some good level land for alfalfa; plenty well water, will be under canal. $2.50 a day and our expenses, if you do not take. U. S. fee 25 cents an acre. A man or woman can take 160 to 320 acres. One man refused $1,400 net the day I located him. You may do better. **If you want this land,** bring your money and **come** to Armona, California. Write me when you are coming, Box 81, Armona, or Route 2, Hanford, Cal., JOE CLARK (farmer.)

GOVERNMENT LAND—LETTER TO inquirers—If you have $160 and want 160 acres good rich soil, fine for poultry, pasture, cows, grain and fruit, near producing oil wells, write me why you do not come to Armona via Goshen Junction, inquire at hotel for my ranch. To get place now—first come, first choice. Bargains. Under improvement plan no more cost for one year, under settlement plan you need not come back for six months, then again six months later. Plenty well water. Convenient to wood for post and fuel. JOE CLARK, Armona, Cal.

rains. Is it water? Would frost or light freezing injure it? Will Acacia Baileyana be injured by standing in water or in lawn that is much watered?—J. D. M., Highland Park.

You do not give any information as to the condition of the tree to show what is the trouble, but from your query we take it that water may have caused unhealthful condition. We have seen Baileyana in lawns where they were heavily watered, and did well. We are sure that no temperature in Highland Park would ever injure the Ficifolia. The damage from water is more evident where land is underlaid with hardpan so as to maintain for a long time a soggy condition of the soil. If the trees are not where the lawn has to be protected, we would advise a deep spading and turning up of the soil, to allow air to enter and create as sweet and wholesome condition as possible. A slight dressing of lime might help to correct poor soil condition.

DR. WHITTLESEY'S VETERINARY REMEDIES.

These are not ordinary mixtures but are from well tried formulas, used in an extensive practice in Southern California for nearly a quarter of a century. Dr. Whittlesey's Sulphur Arsenical Salve for deep fistulous or ordinary chronic, indolent sores such as, "Poll Evil," "Fistulas," "Quitters," "Thrush," "Scratches," "Warts," "Collar sores" or "Sit-fasts." $1.00 per package postpaid. Printed directions. Dr. Whittlesey's Antiseptic Healing Powder. Forms a coating over raw surfaces, excludes air, flies and floating germs. Makes a cheap and convenient dressing for the many sores that occur to stock on the ranch. $1 full pound can postpaid.
DR. R. T. WHITTLESEY.
Veterinary Hospital, 714 East Seventh St., Los Angeles, Cal.

BERRY PLANTS.

STRAWBERRY PLANTS—FINE ONES, strong, thrifty, restricted Kellogg method, best varieties, Marshall, Jessie, Climax, and Everbearing. $3.00 per 1,000, $12.50 per 5,000. To close the season all plants are one-half prices quoted above while they last. Address J. R. POWELL, Ripon, Cal.

STRAWBERRY PLANTS FROM ONE year old plants that have not been allowed to bear fruit. Brandywine and Sharpless. $2.50 per 1,000, 35 cents per 100. R. P. NELSON, San Jacinto, Cal.

STRAWBERRY PLANTS—FINE ONES, strong, thrifty, restricted Kellogg method, best varieties, Marshall, Jessie, Climax, and Everbearing, $3.00 per 1,000, $12.50 per 5,000. Address, J. A. POWELL, Ripon, Cal.

WANTED—LADY THOMPSON, TEXAS, and A-1 strawberry plants, also Loganberry. State number and lowest price. None but first class plants wanted. Address, G. H. HOPKINS & SON, Burbank, Cal.

FOR SALE—BERRY PLANTS; LOgans, Giant Himalaya, Mammoth and Lucretia dewberries. Would exchange for rooted Tokay. A. P. HENNING, box 225, Cottonwood, Shasta Co., Cal.

FOR SALE—LOGAN, MAMMOTH, PHEnomenal, Himalaya, Blackberry, Dewberry; strong plants, $10.00 per thousand. Strawberries, $3.00 per thousand. GRIDLEY COLONY NURSERY, Gridley, Cal.

FOR SALE—BERRY PLANTS, BLACKberry, Dewberries $10.00 per thousand, Mammoth Logan, Phenomenal $1.50 per hundred. H. O. SORKNESS, Hemet, Cal.

FOR SALE—LOGAN BERRY PLANTS well rooted and very strong plants. Write me for terms. Plants ready now. Home 'Phone 2161. Z. A. WOLLAM, Riverside, Cal.

BULLS.

FOR SALE—ONE REGISTERED JERsey Bull. Dam has given 6,300 pounds of milk with this, her first calf. Price, $50.00. GEO. W. THOMAS, West Central Ave., Riverside, Cal.

Household Department

SELLING THE FARM.

Well, yes, we settled, ma and I, that
we would sell the farm;
We are getting on in years and toil
has somehow lost its charm.
So we said we thought it time to lay
some of life's burdens down,
And the married children thought we
ought to buy a home in town.

Well, a purchaser come right along,
for I'll own, I'm free to say,
That a better or a prettier place you
might search for many a day,
With its fertile fields and wooded hills
and meadows lush and green,
And buildings snug and neat and trim,
as any ever seen.

But it's strange how old familiar
things will twine around the heart,
And we never dream how close they
cling till we sense that we must
part,
And when it come to business, sir,
that's what I meant to tell,
We found a precious lot of things that
somehow wouldn't sell.

There's that willow that ma planted
some forty years ago;
It has grown into a mighty tree with
branches drooping low,
And the children played beneath its
shade when the days were long
and warm—
Now I wouldn't sell that willow tree
for the price of this old farm.

And it's curious how we grow to love
the things we plant and tend—
Every tree in that old orchard seems
just like a human friend,
And I couldn't help but meditate how
we'd miss them, ma and I,
The tree of Golden Pippins and the
hardy Northern Spy.

And then the precious memories that
cluster 'round the place—
They seem to fill these homely rooms
with beauty and with grace.
We could seem to see the children
flitting blithely here and there,
And to hear their merry voices call-
ing, calling everywhere.

Then one day I found ma sitting by
the rose bush at the door
With the wistful look upon her face
I'd never noticed there before,
And I just dropped down beside her
and she looked up at me,
And something blurred our dim old
eyes till somehow we couldn't
see.

And then we settled, then and there,
that we'd stay on this old place
Till the Lord sees fit to call us to
stand before his face,
And we're mighty glad to tell you,
sir, we have no desire to roam,
For we think we know just what it
means to sell the old farm home.

—Elizabeth Clarke Hardy.

THE OLD MAN AND THE OLD FARM.

THE OLD man's ideas of farming were peculiar, but then the Old Man was peculiar.

The old farm was his hobby; his wife said he had fallen into a rut, which he could not get out of; that as a farmer he was a dismal failure—but he labored under the delusion that he had brought the farm into a state of perfection, being utterly unconsious of the abject muddle he had made of it.

On one occasion, as he stood in his favorite attitude, his hands clasped behind his back, his tall silk hat tilted on the side of his head, gazing somewhat sadly upon the ill-devised pig pens and dilapidated barns, he said to his foreman, "When I die, I would like to take the old farm to Heaven with me;" then half to himself he added; "But I shall give it away, when I am dead."

One day when the old man was looking at the pigs the choreman told him the old sow had just added a litter of nine to the stock list; "Umph!" he exclaimed, "eleven would have been better."

Then he grew communicative, as was often his habit, when conversing with the men on the farm; "I've bred hundreds of hogs, they never brought what their food cost me, there is nothing in 'em. I've tried dairying too, there is nothing in it."

"Is that so," said the choreman. "Yes," said the old man, "the orchard is nothing but a sheer loss; I've raised hay, corn and grain, and there is nothing in it. My chickens have swallowed up tons of stuff. After the bills are paid nothing remains."

"Indeed," said the choreman, "What is there anything in, Sir?" "Nothing," replied the old man.

"Oh!" exclaimed the startled choreman, "What's a poor man to do for a living?" "Nothing!" said the old man. "I spend all my time collecting money to pay my bills."

The old man prided himself upon being quite a "chicken man," and liked to wander around among the chickens, and was very fond of using the term "thoroughbred" and bestowed the definition upon many a scrub fowl that had no possible claim to the proud distinction. If he could hitch on to the chicken man, he would tell him, "I don't want eggs when they are ten cents a dozen. I want my fowls to lay when eggs are 65 cents a dozen."

When the laying season had just begun, the old man asked, "How many eggs are you getting now?" "About seventeen dozen a day, sir," the chicken man replied. "Ah!" said the old man, "put plenty of straw in the nests, and you will get nineteen dozen a day."

Naturally as the laying season advanced the number of eggs increased, and the following week when the old man inquired again, "How many are you getting now?" the reply was, "Twenty dozen a day, sir." "Umph!" said the old man, loking extra wise, "put in more straw and you will get twenty-five dozen a day."

But the chicken man knew by the number of laying hens that the limit was reached and not a bale of straw in each particular nest could induce the busy fowls to lay one extra, much more dozens.

The Plymouth Rock yards ran down from indiscriminate breeding, and were overcrowded with culls, and ancient blear-eyed scrawny roosters; the chicken man advised the introduction of a fresh strain of well bred birds. "Go and get them," the old man said, "I have no time to go chasing round the country after roosters."

The yards were sorted over, and the old fellows that had fallen into senile decay were turned to wander at large.

When the old man went the round of the yards with all the solemnity of a fancier judging at a poultry show, his man ventured to draw his august attention to the well set up, handsome birds, the newcomers, who were strutting around, crowing lustily in their new quarters.

"You see, Sir," said the chicken man, "What finely marked, vigorous birds you now have; how they show up those outsiders."

Some of the outcast relics lingered

Coulson's
POULTRY FOODS

Special Dry Chick Food

Makes Them Grow

COULSON'S SPECIAL DRY CHICK FOOD, during the five years it has been on the market has justly earned for itself its great reputation as a life-saver for little chicks by its special adaptation to their needs.

THE UTMOST CARE is observed in the selection of each of the dozen or more articles composing this unequalled feed; tender seeds, cracked grains blown free from dust, steel-cut oats, tiny pieces of dried meat and bone, willow and pure bone charcoal, are combined with other very necessary ingredients; every article being selected with special reference to its quality, strength, and desirability for the needs of the young chick.

FOR YOU TO BUY the many different articles composing Coulson's Special Dry Chick Food is quite impracticable; you could not be certain as to their quality for one thing, and the high cost of certain of them when purchased in small lots might lead to their being left out to the detriment of the chick.

TO MAINTAIN the high reputation of COULSON'S SPECIAL DRY CHICK FOOD, nothing is left undone to make it absolutely the best feed that can be made for the little chicks.

COULSON'S SPECIAL DRY CHICK FOOD can be fed exclusively to your little chicks for the first six weeks, at a cost of about four cents (4c) each; and what is of still greater importance, it will do all that can be done in the way of feed to bring them through that critical period of their lives in full health and vigor.

TO RAISE EVERY CHICK you hatch; to have fine, large, healthy chicks; to have chicks that will stand up and crow when eight weeks old; to raise chicks that you will be proud of, FEED COULSON'S SPECIAL DRY CHICK FOOD, THE LIFE SAVER.

Angle Lamp

The Light That Never Fails

Thousands in use all over the country. A good light is the greatest pleasure and the first necessity of every home.

The only lamp on the market that is sold under an absolute guarantee.

Remember, the light from Kerosene is the light science has agreed upon as being the purest and best, because it is soft and mellow and restful to theeyes.

Here are a few of The Angle Lamp Merits:

NO UNDER SHADOW. NO SMOKE, NO ODOR, LITTLE HEAT.

GREAT ECONOMY—COST LESS TO BURN than an ordinary lamp. As easy to operate as gas or electricity, and better than either. ABSOLUTELY SAFE under all conditions. Lighted and extinguished like gas. Burned HIGH or LOW like GAS without a trace of odor. And a BRILLIANT, soft, steady, shadowless light—but this you will have to see to appreciate.

The lamp as shown in cut burns 22 hours on 3 quarts of oil.

Hop prices are looking up somewhat

outside the wire enclosures, evidently dissatisfied with their freedom, hungering after the good things inside.

The old man looked at the fine new birds, then glanced dubiously at the ancient "scrubs" outside the pale; his belief in them as "thoroughbreds," must have fallen shattered to the ground, but the obstinacy of his nature made him reluctant to accept the evidence before him.

However, there were very few corners the wily old man could not wriggle out of, so turning to his man, he remarked with set visage and convincing tones, "Well, they were 'thoroughbreds' when I bought 'em."—C. H. Simson.

About the House

IF SOME day you want a dainty luncheon dish, serve bacon and eggs in a new way. Cut some slices of bread into pieces three or four inches square, then cut each piece diagonally across and toast lightly. Arrange the pieces on a platter, keeping the square form. Broil very thin slices of bacon to the curling point and place a slice on each square of bread. A poached egg with the white neatly trimmed to leave an even rim is slipped on to the toast and bacon. Have ready a hot tomato sauce, of the consistency of thick cream, and pour around the eggs. Place a little parsley or cress at each end of the platter, and serve immediately.

Crackers dried in the oven before being rolled will be much lighter for puddings and "crumbing" and better flavored too.

The troublesome paint stains on the floor may be scoured off by covering them with turpentine or benzine and after a short time rubbing them with emery paper, or a little pulverized pumice stone, applied with a damp cloth. Have no fire or light in the room while using the benzine and turpentine.

Whenever I find any new and easy way of making "left-overs" palatable, I like to pass it on. In my cupboard the other morning I found a saucer of plain boiled rice and a bowl of chipped dried beef that had been cooked in a cream sauce. I put them into a saucepan and in less than five minutes I had a hot dish for breakfast that every one approved of.

If you have some slices of cold roast beef, pork, or mutton, you can make them into a palatable hot dish by cooking the meat in a tomato sauce until the meat is hot and then carefully lay the slices of meat on a platter and pour the sauce over it; or you may lay the meat on slices of hot buttered toast before covering with the sauce.

One way to make the sauce is to take one pint of tomatoes, two teaspoons of sugar, eight peppercorns, one half teaspoon of salt and a bay leaf. Cook for twenty minutes, strain and add one cup brown stock. Brown together four tablespoons butter and four tablespoons flour—by browning you get a red sauce instead of a pink. Pour this into the hot tomato and beat until smooth.

Most people like "noodles" in soups and this recipe was given me by a cook who had a neighborhood reputation for "noodles." One egg, half an egg shell of water, flour to make stiff enough to roll. Roll very thin, fold over and over, then slice thin, shake out and drop in boiling soup or gravy. Cook ten minutes.

Sometimes "our folks" grow tired of potatoes and carrots and will have none of them, but they welcome "Potatoes Finnegan" and "Potatoes Finnegan" are just potatoes and carrots cut in dice or small cubes, seasoned with butter, pepper and salt, and then a thin white sauce poured over them. A tablespoonful of chopped parsley may be added.

If the spring winds roughen your hands, try washing them in buttermilk every night. If your finger nails are brittle and break easily, rub them with vaseline or olive oil before going to bed. You can keep the oil from the bed clothes by drawing on a pair of gloves or mittens.—Elbepe.

• • •

Hair Chain.

Will you please tell me how to make a hair chain? I mean a chain out of human hair. Will you also tell me how to fix a hair chain for a watch.—Mrs. F. E. S,, Riverdale.

I am very sorry, but I have looked very hard without being able to find directions for making a hair chain. Such chains are very pretty and I hope some of our subscribers know how to make them and will furnish the directions. I presume you would have to take the finished chain to a jeweler to be mounted with the proper clasp and attachments. At least one very beautiful one I have seen was so treated.—Elbepe.

A HAY COOKER.

A SUBSCRIBER sends in directions for making a "hay cooker." It can be easily made at home by any "handy" man or woman. It is a saver of fuel, there is no odor from the cooking, and no worry for fear things will burn. Any foods that should be cooked slowly can be cooked to perfection in the "cooker." Sometimes you may have to take the kettles out and heat the food the second time, but that is very little trouble and it is only for a few things that a second heating is necessary.

The box must be made of thick firm wood—an old trunk will do—without cracks or holes, and must have a well-fitting lid. Put three inches or more of packing material all over the bottom of the box. The packing material may be wool, cotton, crumpled bits of paper, feathers, hay or excelsior. Choose your cooking vessels with good, tight, well-fitting lids and avoid tin as it rusts quickly. Shape around each vessel some sheet asbestos, coarse straw paper, or corrugated paper, fastening it with stitches or a few rivets. Set the kettles in these coverings on the layer of packing in the bottom of the box, then stuff the packing all round them, and pack it firmly. Then make a cushion to cover all, fitted to the lid, which must fit closely. There must be at least three inches of packing between the kettles and the box—more is better—and there must be more if hay is used for the packing. Spare no pains to make the box air-tight.

Take the kettles from the cases leaving the cases in the box, put the food in the kettles and put on your cooking stove. Bring to a boil and cook for five or ten minutes, then quickly set the kettles in their cases, cover with the cushion, and fasten the lid. Food that requires one hour over the flame of a gas stove will require about three or four in the "box."

Some recipes came with the directions for making the "box."

Apple Sauce.

Make a syrup of one cup of sugar

and one cup of water. Into this slice about eight good sized cooking apples. Boil for five minutes, then put in box all night.

Corn Meal Mush.

Into five cups of boiling salted water stir slowly one and one half cups of cornmeal. Cook about five minutes and place in box overnight. A large quantity will cook better than a small amount.

Corned Beef.

Place three pounds of meat on fire, covered with cold water. Bring to the boiling point, pour off the water, cover again with cold water and add one level teaspoon of sugar. Leave it in the box all day. In the middle of the afternoon, take from the box, re-heat and replace. It will then be hot for the evening meal. If any is not eaten it may be returned to the liquor and used cold or made into hash.

Macaroni.

Cook about ten minutes on the fire and two hours in the box; then bake as usual.

Rice.

One cup rice, five cups boiling, salted water. Boil about five minutes on the fire and leave in the box six hours or over night.

Lamb Stew.

Cut in small pieces about two pounds of lean lamb, one onion and one carrot. Brown these in skillet with a little butter. Then add a pint of water, a pinch of sugar, a dash of pepper. Place in the kettle and simmer about twenty minutes. Add a level teaspoon of salt, let boil, and place in box for six hours. Take from the box, place on fire and add a cup of cooked peas if you have them, although it is very good without, and a few drops of Worcestershire sauce and thicken the gravy as desired.

Potatoes.

Potatoes cut small should be cooked for five minutes on the stove and in the box for two hours. Drain, season and mash as usual.

Spinach.

Wash thoroughly, cook on stove for five minutes, then in the box for two hours. Season as desired.

Spiced Prunes.

Make a spiced vinegar (tie the spices in a bag), sweeten to taste and pour over large prunes that have been soaked for 12 hours. Boil ten minutes and leave in the box 12 hours.

Cherry Tapioca.

Soak one half cup tapioca over night. Drain a can of cherries and add two and one half cups of the cherry juice to the tapioca. Sweeten to taste and boil for three minutes. Place in the box for two hours, then pour over the cherries. Serve cold with cream, either plain or whipped.

A BOILED DINNER.

While much depends upon the quality of the corned beef, even more depends upon its proper cooking. Most persons think that anyone can cook a New England boiled dinner, but there was never a greater mistake. Even with high-priced cuts rapid cooking will toughen or reduce it to a mass of strings. The brisket or loose flesh below the neck is in great demand for an economical family dinner. It is juicy and with the proper proportion of fat mixed with the lean.

The rump is good for slicing cold, if one does not care for any fat, says Emma Paddock Telford in the New York Evening Telegram. The plate and navel are cheap and good for corning, though rather fat. If you do not care to corn your meat at home, as most English housewives do, it is a good plan to select the cut you like and ask the butcher to corn it for you. Leave the meat in this process for two or three days, no longer.

A good pickle that you can make at home calls for three pounds rock salt, a quarter pound of brown sugar and a half ounce of saltpeter, with water enough to make six quarts. Boil and skim. Drop in a raw potato and if the brine is strong enough it will float. Make the day before using, so that it will be absolutely cold, when the meat goes in. Keep in a stone jar with cover, having a plate with stone on top of the meat to keep it under the brine.

When ready to cook wash the meat in two or three waters, scrape, put in a pot and cover with cold water. Allow 20 minutes to each pound and turn the meat two or three times while cooking.

After the meat has come to a boil and has been skimmed, push back on the fire where it will simmer. If you are going to use the meat cold let it cool in the liquor in which it has been cooked. Otherwise save the liquor and put the meat left over from dinner in the pot liquor, leaving in over night.

The vegetables that go with a boiled dinner are cabbage, beets, potatoes and if desired carrots or turnips. Each should be cooked separately, but with some of the pot liquor to season. Cabbage is often cooked with the meat, putting it in (quartered and cored) about an hour before the dinner is served. Beets in the summer take but 20 minutes or half an hour, but winter beets need as long or longer cooking than the meat. When serving, arrange the meat in the center of a large platter, then put the vegetables in groups around the meat.

WEAVING.

Spinning and weaving were among the earliest arts and were practiced by the savage tribes in a form which would seem to us in this enlightened day and age to be of the crudest kind.

The complicated weaves of today are but the development of matmaking and basketry made by the savage tribes. At this time cloth was not woven into bolts of many yards in length, but into the shape and size for the purpose for which it was designed, the design obtained from the objects by which they were surrounded. Never did they allow their decoration to interfere with its use. The skins of animals were used for clothing fastened together by the use of thorns for needles and the sinews of animals for thread.

The word textile means any kind of woven fabric made from wool, cotton, silk, flax, hemp, ramie, goat, camel's hair, and beaver, or the filaments drawn out of gold leaf or any other metal, all of which are webs formed for textiles.

Cotton is the most important of all vegetable fibers, three-fourths of which is raised in the United States.

Next in value is wool. Its great value lies in the fact that it is strong, elastic, soft, very susceptible to dye,

EUCALYPTUS TREES.

The great interest which has been manifested in eucalyptus planting this season has exhausted many stocks and inquiry is made as to the supply meeting all demands. The Morris & Snow Seed Co., of 425 South Main St., Los Angeles, finding its stock getting low recently made a purchase of the Eucalyptus Land & Timber Co., of Inglewood, of over two million trees. But out of that immense number only about 400,000 trees remain.

In these 400,000 tree are Rostrata, Robusta, Tereticornis, sugar gum and Resinifera. The Rostrata is the largest number of all the immense stock.

The wise planter will get busy before the trees in hand are all exhausted.

The Southern Pacific Railway Company is installing 6,000 feet of 6-inch Machine Banded Redwood Pipe with cast iron collars, pipe manufactured by the National Wood Pipe Company, Los Angeles, California. The Wood Pipe is being laid in a salt marshy ground. Water will be piped from the Hope Ranch to the station yards.

Anthrax Cure, Milk Fever Outfits. See O. J. Weber Co., 225-227-229-231 East Sixth street, Los Angeles.

San Francisco Markets

SAN FRANCISCO, March 2, 1909.

Butter.

A decline of one cent is noted in the butter market. Fresh stocks are steady with storage showing little interest.

Hay.

Hay is higher, and we might say materially higher too, for dealers and all interested seem to have come to the realization of the fact that the available supply might not be enough to take care of the demands which are bound to be made on us. Receipts for the past week have amounted to 2300 tons, being practically the same as the amount received the week previous. Business is good and the demand both in San Francisco and the country is very heavy. Consumers as well as dealers seem to appreciate the gravity of the present situation and many are making efforts to contract for their supply of hay for the remainder of the season, thereby protecting themselves against higher prices which in our opinion are bound to come. Many think that we will have a hay famine but this connot be, for feed must be obtained for all stock even if we have to draw from outside States which at present can only be done at prices higher than are now ruling locally.

The most peculiar feature at present is the small range of prices, the medium and poorer grades of hay being very hard to find and as a result we hear the expression "hay is hay" irrespective of quality. The only kind of hay which is at all reasonable is stock hay which cannot be used for work horses or dairy cows; even this grade has advanced in sympathy with the general market.

Choice wheat hay .....23.00@24.50
Good wheat hay .....21.00@22.00

Citrus Market

LOS ANGELES, March 3, 1909.

The shipments during the past few days have been exceptionally heavy. The shortage which occured in the Eastern market during the recent storms was so great that shippers seemed to feel that great quantities of citrus fruit would be absorbed, in fact, such has been the case, and the situation has been helped by the shortage of bananas and some other tropical fruits. However, the citrus shipments have been so exceptionally heavy, exceeding

Cream Separators, all sizes, all prices. O. J. Weber Co., 225-227-229-231 East Sixth street, Los Angeles.

200 cars per day on many days, that the market has been to a certain extent, unsettled. There is as yet no slump in prices, although some shippers have been a little finicky and agreed to shade general quotations 10 to 15 cents. The larger shippers, especially the Exchange, have taken hold of the situation, however, and shipments are being slowed up so that it is thought the conditions will be corrected within a very few days.

This is the harvest time of the entire year and the best prices should prevail, especially after fruit has been carried over the months of January and February, with fair returns being secured.

Lemons are going forward fairly rapid now and are commanding good prices; foreigns are coming in in about the same quantity as formerly but the warm weather which has prevailed in some sections has aided in the disposal of stocks on hand.

Shipments.

Shipments of oranges to date, since November 1, 1908, aggregate 8,332; lemons 1,515, or a total for this season of 9,847 of citrus fruits. This date last season, the shipments were 8,505, of oranges, 1,467 lemons, or a total of 9,972 cars.

NEW YORK, March 1.—Forty-five cars navels, one car navelencias and five cars lemons sold. There is a good demand, but prices are lower on navels. The market is steady on strictly fancy lemons, but weak and lower on ordinary stock. Weather clear and favorable.

MEALY BUG.

(Continued from Page 245.)

ty well over them. At the present time there is very ittle mealy bug to be seen, and the general condition of the orchards in that respects is indefinitely better than it was last spring and summer.

Besides the Cryptolaemus, last summer George Compere brought to us from Japan three different species of parasites which feed upon the mealy bugs there. Two of these resemble very much the Scutellista, and the other is a yellow lace-winged fly. All three are very small and difficult to detect in the open. I feel very sure that I have seen the yellow fly and the larger black flies, and therefore hope, and really feel some confidence, that they are domesticated with us.

I feel that the only hope of keeping the mealy bug in control is by parasites, precisely as with the cottony cushion scale. It is idle to think of eradicating them by fumigation or sprays, after they are once well established in an orchard, though it is possible that, if taken in the very first instance, this might be done. This last fall we tried putting 16 ounces of cyanide over a moderate sized lemon tree and leaving on the tent all night. Though a good many bugs were killed, we had no trouble in finding plenty of live ones the next morning. I have found them in masses three or four inches below the surface of the ground wherever there are cracks between clods. Therefore it seems clear to me, as I said before, that our only real hope is the parasites, for these will follow the mealy bugs wherever they go.

You ask about the Bonnie Brae ranch. I have received and packed all the fruit grown on this ranch throughout the past year. When it was in its worst condition, a great deal of the fruit had to be thrown away. That which we received was washed by putting kerosene in the tank of our lemon washer, and in this way we cleaned it up satisfactorily, and it seemed to keep fully as well, if not better, when the kerosene was used. The mealy bugs multiplied upon this orchard so that at one time the trees were literally white with them, and there would have been no difficulty in filling a five-gallon coal oil can from a single tree. I hope that these parasites are now so fully established that they will hold the mealy bug in subjection, just as the Vedalia does the cottony cushion scale. It will take at least one year to demonstrate this, but it certainly looks much more hopeful now than it did a year ago.—R. C. Allen, Bonita.

CALIFORNIA HORTICULTURE, THE FRUIT GROWERS GUIDE.

Meets with pronounced success. The demand for copies of this work is increasing. Orders are coming from all parts of the country. It is a very exhaustive publication. Describes fully 2,000 different varieties of trees and plants. Is superbly illustrated and contains much valuable information to planters. Copies may be had by sending 25 cents in stamps to George C. Roeding, Fresno, California.

WHITE WYANDOTTES.

A very neat folder of eight pages is issued by the Mission View Poultry Ranch, of which Mrs. C. D. Hubbard is the owner. Every page is decorated with photographs of the magnificent stock which Mrs. Hubbard is noted for breeding. She probably has the longest string of winnings of any Wyandotte breeder in the country. She not only has prize winners but also birds which prove their worth at the nest. Mrs. Hubbard goes to the limit in her guarantee of her eggs as she states in this circular, "all clear eggs replaced if returned within nine days, express prepaid." All of Mrs. Hubbard's breeders are trap nested.

FINE TURKEYS.

Mrs. M. E. Sherman of Fresno, writes the Cultivator that she has just received some Turkeys from the J. R. Snead Ranch at Dixon, which she secured through an ad in The Cultivator. Regarding them, she says, "They are very fine birds, and we are pleased with them. Only nine months old and taller than others I have seen three years old. Of course, they are not larger, but taller. When they fill out, they will weigh 40 pounds. I bought Bronze Turkeys for many years, but these are the finest I have ever gotten for my money."

IF THESE PEOPLE CAN USE THE ELIXIR WITH "ENTIRE SATISFACTION," YOU CAN.

Tuttles Elixir Co., Gentlemen:—We have used your vertinary remedies for the past season with entire satisfaction. Through the Mud Fever contagion of last spring, Tuttles Elixir did splendid work for our horses. They worked in the worst part of the city, but with good care and a liberal use of Tuttle's Elixir they came through in good shape.—P. L. Bonebrake, Yardmaster, Cudahy Packing Co.

Send for a free Veterinary Book to Willis A. Shaw, Manager Pacific Coast, 1921 New England Ave., Los Angeles, Cal.

A deposit of gypsum estimated to contain over one million tons of a high grade gypsum and gypsite has been discovered in the Temescal mountains and is being developed by Bollinger & Crane of Riverside. The gypsite is a disintegrated gypsum, showing a high analysis in sulphate of lime, and is a very valuable form of lime for agricultural purposes.

The Morse Institute of Telegraphy now advertising in the Cultivator reports a large demand for competent operators and are soliciting students. Applicants will be furnished full particulars in regard to entering the school, cost, etc., by addressing Morse Institute of Telegraphy, corner Market and Jones street, San Francisco, Cal.

Don't Wear a Truss

After Thirty Years Experience I Have Made A New Discovery For Men, Women or Children That Cures Rupture.

Costs You Nothing To Try It.

If you have tried most everything else, come to me. Where others fail is where I have my greatest success. Send attached coupon today and I will send you free my book on Rupture and its cure, showing my new discovery and giving you prices and names of many people who have tried it and were cured. It is instant relief when all others fail. Remember I use no salves, no harness, no lies.

I send on trial to prove what I say is true. You are the judge and once having seen my book and read it you will be as enthusiastic as my hundreds of patients whose letters you can also read. Fill out free coupon below and mail today. It's well worth your time whether you try my discovery or not.

FREE INFORMATION COUPON

C. E. Brooks, 9790 Brooks Bldg., Marshall, Mich.

Please send me by mail in plain wrapper full information of your new discovery for the cure of rupture.

Water in the San Joaquin Valley

Head of the Irrigation System, Sanger, California. A Perpetual Water Right Which is Appurtenant to Rich Valley Land

See That Can? It Never Moves!

Other separator manufacturers have been trying to imitate it for five years. That shows their high opinion of a low, steady supply can which need not be moved in order to take the bowl out of the machine.

1909 TUBULAR "A"

Exclusive Tubular advantages are surprisingly numerous. Observe the low supply can, so easy to fill, not necessary to move to take out bowl. The solid, one piece frame. The suspended bowl and bottom feed, Enclosed, self-oiling gears. The plumb bob, at back of machine, for quick, easy leveling. The crank set just right for easy turning.

OUR machines are the **only** cream separators that have such a supply can. Other manufacturers have **not been able to imitate it.** That is because all common "disc" or "bucket bowl" separators have bowls fed through the top—such bowls **must** have the supply can set directly over them. Consequently, the supply cans are always the highest part of all common "disc" or "bucket bowl" machines and must always be lifted off before the covers or bowl can be removed.

LOW supply cans, which need not be moved, are **only possible** in cream separators having a **suspended bowl fed through the bottom.** Our machines are the **only** cream separators having such bowls, and our patents prevent any other manufacturer from making them.

SUPPOSE you had the supply can, on any separator, full of milk and found it necessary to remove the bowl? It would be mighty inconvenient to lift the supply can off, wouldn't it? No need to with the Tubular.

PUBLIC appreciation of Tubulars has made the Tubular cream separator works the biggest and finest in the world. We have additional factories in Canada and Germany. 1908 sales were way ahead of 1907--far ahead of any competitor, if not all competitors combined. The additional good features in our 1909 Tubular "A" have already made the Tubular even more popular than before. Write for catalog No. 260.

The Minus Quantity in California Soils

An Address by Prof. G. W. Shaw of the Cereal Investigations of the State University at the Last State Fruit Growers Convention

UNDER the above title the writer proposes to set forth what he believes to be the most vital question confronting the farming and horticultural interests of California today. I may perhaps be pardoned for saying that this impression has not been formed hastily, but is the crystallization of a somewhat careful study during the past seven years both in the field and laboratory of the soil conditions as they obtain if not in all, still in most parts of the state.

While these investigations have had mainly to do with the underlying causes for the low average production per acre of field crops, particularly grain, yet in the prosecution of this special work I have become impressed with the unmistakable fact that many fruit and vine growers in Northern California are facing much the same problem.

In the case of the general farmer the gradually reduced wheat yield per acre leading to a change from wheat growing to barley growing, and the subsequent gradually diminished yield of this crop has forced him to ask the very pertinent and fundamental question, "Why are soils which in our fathers' hands were so productive now giving so meager returns?" This is still more evident in the case of the fruit grower by his blind rush to the commercial fertilizer market for some sort of a cure-all to remedy a condition that he sees is already upon him or one which he wishes to avoid.

The Popular Explanation.

The general supposition, though erroneous, is that plant food content if not absolutely gone is reduced to a minimum—that the soil is exhausted. Both the supposition and the usual conception of the meaning of the term fertility are incorrect.

The chemical phase of the subject is over-emphasized. The terms plant food and fertility are not synonymous. The latter refers only to the ability of the soil to produce crops, and the plant food of a soil is only one of the attributes, and often not the main one in crop production. Moisture, warmth, and aeration; soil texture, soil fitness; its tillage, drainage, and irrigation, are all quite as important factors in the productiveness of fertility of a soil as are fertilizers. The crop producing power of a soil constitutes its fertility and not simply the three or four forms of plant food present, and the maintenance of fertility involves such an all-around handling as will conduce to maximum effectiveness. Both science and the better practice is laying more and more stress today upon the direction of natural forces, the same that built the soil in its pristine vigor of years ago, on the conservation of the inherent richness of the soil, and on the acquirement of plant food supplies from the air and the subsoil, but the popular mind is still fixed on the idea that a fertilizer is a panacea for all soil ailments. The purchase of plant food when needed is an important matter and should not be neglected, but no fertilizer can act as a substitute for proper soil management.

There are, of course, soils and soils, some which from the outset are relatively unproductive unless assisted; others which are at first fertile but which become rapidly depleted; and still others which maintain high productiveness for many, many years. But the best of them show wear if improperly managed; yet even though they may have been grossly abused most of them may be renovated.

Neither the cereal nor the horticultural soils of California are exhausted or worn out—many are depleted, but there is an immense amount of inherent richness in most soils, even in the poorest. In a certain table which is supposed to show 15 representative samples of so-called "worn out soils," the nitrogen content in but one sinks below 1,100 pounds in the top eight inches, and but twice below 1,500 lbs.; the phosphoric acid content but once falls below 1,000 pounds, and but three times below 1,500 pounds; while the two lowest potash contents are 1,000 and 1,200 pounds and the next lowest is 4,000 pounds. The average nitrogen content of these soils is above 3,000 pounds, 5,000 pounds phosphoric acid, and 17,000 pounds potash in the top eight inches, and these figures may be ordinarily doubled for the next eight inches will usually show as much as the top, and is available for most crops. If we compare these figures with those indicating the draughts made by most crops the supply of plant food would not be exhausted in 500 years.

The figures express for the most part latent rather than potential plant food and are merely given to enforce the thought that soils are seldom if ever denuded of their plant food entirely. The causes of lessened crop production lie partly in a shortage of soluble plant food, for only a small amount of the total plant food is potential at any one time, but is more often the result of a wretchedly bad soil management on the part of the grower himself. We have not given the ounce of prevention and consequently we must pay for the pound of cure. Nature made the soils of our valley friable and absorptive, but we have sacrificed this condition for the immediate dollar, and now we must pay double the price to restore it. Nature will restore the condition but she is unrelentingly slow.

This minus quantity of our soils lies not so much on the chemical side of the soil as upon the wretchedly poor physical condition induced through the lack of any attempt to return to the soil that vital attribute which makes for productiveness, humus, which together with rational tillage and the use of manures constitutes the best key for the unlocking of the latent plant food mentioned previously.

Failure to realize the importance of this most vital question,—the restoration of humus,—has led to lessening the retentiveness of our soils for moisture, especially in the upper layers, a very serious matter in our climate of fickle rainfall; a lessening of available plant food; the making of the soil colder, and the increasing of the cementing action in the case of heavy soils and increasing the tendency of light soils to drift.

The maintenance of fertility or productiveness of soils is very largely a matter of the up-keep of its humus content. The "first aid to the injured soil" abused and depleted, should invariably be to supply it with a good quality of humus. We shall not attempt at this time to go into a scientific discussion of what humus is, but shall pause only long enough to say in this connection that humus is a variable, indefinite sort of matter, difficult to classify chemically, complex, sometimes highly nitrogenous and sometimes nearly nitrogen-free, composed of mixed animal and vegetable matter—mostly the latter—in its intermediate forms of decomposition, far along in decomposition, but not complete. It is the result of the partial decomposition of the organic matter of soil, leaves, sticks, straw, stubble, roots, sod, green crops turned under, and the like.

Both Chemical and Physical.

During its process toward final destruction, and while being made into mold, this material is useful to the soil. It was that which gave the lightness and tilth to it in the earlier days through its accumulation for countless years, and which when many began to cultivate the soil was rapidly destroyed. During its formation it acts both in a chemical and physical capacity, which may be summarized as follows:

It benefits the soil chemically:

1. By supplying nitrogen directly;
2. By supplying phosphoric acid, potash, and lime indirectly.

It benefits the soil physically:

3. By augmenting its water-holding capacity;
4. By increasing its warmth;
5. By bettering its texture.

It benefits the soil biologically:

6. By affording food materials for micro-organic growth.

Humus as a Supply of Nitrogen.

The nitrogen of the soil other than that captured from the air by means of leguminous plants is of humus origin. This is a raw material from which nitrates are formed. Humus obtained from different sources carries different percentages of nitrogen, that obtained from stable manure and from leguminous crops being of the most value. It is generally stated that the humus content of the soil extends only to a depth of eighteen inches to two feet, but extensive experiments recently conducted in California on soils which have been cultivated to grain for many years show that the humus content extends very much deeper than this, even to the extent of six or eight feet, but the important fact is also developed that in this soil which has been cultivated for so many years the top foot carries only about one half as much humus as does the second foot, and is in much poorer tilth than the second foot. This means that from a chemical standpoint so far as nitrogen is concerned, in the case of deep-rooted plants, if we take pains to maintain the humus already there found and restore the content of the top foot, we shall continue to have soils which are well supplied with nitrogen. The top foot of this soil, however, is in extremely bad condition, which becomes evident from its great tendency to dry out rapidly and to become very cloddy and heavy.

Humus as a Supply of Mineral Plant Food.

During the processes of humification acids are formed capable of dissolving more or less mineral matter. The weight of evidence seems to show that potash, lime and other mineral forms of plant food are combined with the humus and in

With the Citrus Growers

VALUE OF ORGANIZATION.

Already Porto Rico fruit growers are feeling the need of organization to secure proper returns to the producers. A recent issue of the Porto Rico News touches upon the requirements of that island and in support of its position for the growers standing together, quotes regarding the California Fruit Growers Exchange from the Washington Herald, which is good reading even for Californians who have pride in the fact that one of their great institutions is worthy to be used as a model for the world. The News says:

"Reference has been frequently made to the similarity of the present situation of fruit growing in Porto Rico with that of the early days of California and Florida. If the road lies clear before us why waste time in attempting short cuts only to be turned back by obstacles to the road we should have been following all the time. United effort is absolutely necessary for the prosperous future of the fruit growing industry of Porto Rico and upon each of us it devolves to delegate a small share of his independence of thought and action for the good of the whole."

The News then quotes from the Herald:

"But an orange grown is of very little account unless it can be sold at a profit. When Southern California first began to produce citrus fruit in considerable quantity it was found that it was so far away from the populous centers of the east, where it must find consumers, that the profits were often wiped out by freights and commissions. Men worked long years and planned skilfully, only to have the return from their fruit shipments "come back in red"—the fatal red ink of the account ledger.

"So it came about that economic science was applied to the packing, shipping and marketing of the fruit, completing the circle of scientific progress which wraps the oranges from the blossom to the breakfast table. The growers in each community formed local packing organizations, they in turn formed district organizations, and the district bodies formed a central concern, which is now known as the California Fruit Growers Exchange. This scheme of organization was worked out slowly and gradually, a step at a time.

"The first movement toward intelligent co-operation was the result of the disastrous years of 1892-93. That year not only many growers had to furnish their entire crop for nothing, but to pay the packing and fruit charges besides, as the gross sales of the fruit in the east would not cover the expenses. Then a convention met, its declared purpose being to 'provide for the marketing of all the citrus fruit at the lowest possible cost under the uniform methods, and in a manner to secure to each grower a certain marketing of his fruit, and the full average price to be obtained in the market for the entire season. This purpose has been accomplished.

"In the old days the growers were all in cut-throat competition with each other. There was no such thing as uniform grading and packing. The packing cost the small grower much more in proportion than it did the larger grower, the oranges were sold through speculative commission merchants, and all hope of profit was buried under the mountain of packing oranges, freights and commissions.

"Now the central exchange buys material for packing in immense quantities for distribution among the co-operating packing houses. Nails are bought by the trainload, "shooks" for the boxes on enormous contracts. There is a uniform system of packing and branding which not only rewards the grower of the best fruit for his skill, but which assures the consumer of a high and uniform quality. The exchange maintains offices in all the principal cities of the country, and in the European capitals, through which the product is distributed.

"This co-operative system enables the growers to market their product with all the advantages of modern methods of business which are usually accredited only to "trusts." The exchange is not a trust, however, in that it does not fix prices and that its work is done without contemplation of a profit for the central organization. The packing, handling, and distribution of the fruit is done at cost.

"The annual business of the exchange has grown so that its net profits are now more than $12,000,000 annually. Of course, this exchange does not handle all of the output of the citrus region. Ten years ago its shipments were 25 per cent of the total. This year they will be more than 60 per cent. The larger private growers handle their own fruit and there are other co-operative associations which take care of the output from many small growers. Including these, about 80 per cent of the total crop is marketed on the co-operative or direct basis and only 20 per cent is handled by commission merchants.

"Progress is never content and never stops. The California Fruit Growers Exchange, now that it has a profitable entrance to the markets of the country, is engaged in efforts to improve the market by increasing the demand for its product. The first attempt ever made by a systematic advertising campaign to increase the consumption of a natural product of the soils is to be credited to this organization.

"The experiment was tried three months ago. Iowa was selected as the state for the trial, on account of the fact that the office of the exchange in Des Moines covers the entire state and does not lap over into any other state.

"A special train loaded with oranges from the 4,000 co-operative orange groves of Southern California was despatched from Los Angeles to Des Moines. Daily newspapers in every Iowa city heralded the coming of the "Iowa Orange Special" in half-page advertisements paid for by the Exchange. This was supplemented by advertisements of the local fruit dealers announcing a special Orange Week. Oranges were extolled as: 'Just the spring tonic needed for yourself and children. Nothing in the way of fruit has so much tonic value as orange juice. An orange with every meal means increased appetite, bet-

ter digestion, a clearer brain, and a better constitution in every way. Oranges are prescribed by physicians for their medicinal properties and for their food value to nerve and brain. All during the warm, enervating spring and summer weather, orange juice is most cooling and refreshing.'

"The best skill of the ad writer was employed, dates of the orange week were emphasized, and the demand was made that the consumer see that the name of the California Fruit Growers Exchange was on the box. The result was a wonderful stimulation of the habit of orange eating in Iowa. The advertising will be kept up in a smaller way for a while. If the orange consumption in Iowa is permanently increased, as the heads of the exchange believe it will be, then this advertising campaign will be extended to other parts of the country and will be continued indefinitely. The theory is that people would eat more oranges and other fruit if their attention were called to it by the same methods which have so greatly increased the consumption of the cereal breakfast foods.

"Truly, progressive science has done wonders for the citrus fruit section of California. The beautiful orange groves, with their trim trees of dark green, embellished with golden globes, tell a story of conquest of the arid desert, of the conquest of pest and disease, of the triumph of the horticulturist in improving nature's own product, of the annihilation of distance which intervenes between the grower and the eater."

THE ORANGE IN FLORIDA.

The orange is the leading tree fruit of Florida and up to the year 1894 it might be said to be the only one in which an interest was taken by resident and non-resident owners. But the lesson of the 1894-5 freeze was taken well to heart by those who were permanent residents. Gradually, diversification of crops, especially along vegetable lines, introduced an element from which an annual income was derived while waiting for the orange trees to be rehabilitated and become once more a source of profit.

But the great orange groves belonging to non-resident owners fared worse. So many were abandoned that it seemed as if Central Florida was given up as an orange growing section and this important industry turned over to the lower counties of the peninsula. Though it was not the first time that Florida orange growing had received a serious setback, one had but to recall seasons of drought, of early and late frosts, of destructive insect pests against which the Northern horticulturists have to contend, to realize that nowhere is there perfect freedom from failure, and that Nature, though often dealing blows, endeavors as soon as possible to make up for them.

The five million box mark reached in the season preceding that freeze has not yet been restored, but the number of non-bearing trees reported in 1905 leads to the belief that, in two or three more years, it will be. One and three-quarter million of such trees were added in that year to the one and a half million in bearing. Two years have elapsed since then, and it is safe to assume that there are close upon five million bearing and non-bearing orange trees in the groves of Florida today—these, in about one-half the counties in the state of which the seven principal ones are Brevard, DeSoto, Hillsboro, Orange, Polk, Putnam and Volusia.

About three million boxes was the record for 1905. Owing to the unusual drought that prevailed in 1906 and also in the early part of 1907, this record has not been maintained, though the increase in bearing trees has kept the yield in the neighborhood of two and a half million, with fairly good prices, the valuation being figured at $3,356,609, or about $1.12 per box. At one dollar per box as an average price there is good money in growing oranges in Florida despite the competition from home states and the West India islands, and even Mexico, which is coming into importance as an orange growing country.—Florida Fruit and Produce News.

The Y. M. C. A. of Riverside is giving a practical course of lectures on agricultural subjects. Lemon pruning was the subject of a recent meeting.

DEAD CITRUS WOOD

Is more or less prevalent in every orange and lemon grove, i. e., trees that are unprofitable. How many such have you in your orchard? Would it not pay you to put paying trees in their stead?

Your Home Grounds

Should contain at least a few trees of the better varieties of oranges and lemons. For this purpose we have some exceptionally fine trees to offer, being grown as specimens. Possibly you would like to plant a few citrus trees about your home this season. If so, will you do us the favor to correspond with us about it?

Citrus Fruits

Historically, Horticulturally, Commercially.

Our new booklet gives more valuable information about varieties, methods of planting, cultivating, pruning, picking, packing and shipping than anything of its kind ever issued. Sent anywhere for the small sum of 25 cents. Correspondence a pleasure.

IRRIGATE FROM YOUR OWN RESERVOIR

A reservoir on your own land makes you independent on the water question. You will have no trouble in filling the reservoir during the spring rains, when all the streams, little and big are flooded.

Then you will not be at the mercy of ditch owners and other water users when the dry season comes.

The few acres you will require for the reservoir will not be wasted. They will serve to make all your other lands vastly more valuable.

Raise the Water With An I. H. C. Gasoline Engine

Of course you cannot have your reservoir on your high ground. Locate it on the bottom land where it is easiest made and certain to be filled with drainage waters. Then pump the water wherever you need it with an I. H. C. gasoline engine.

These engines, always powerful and reliable, have been found to be excellently adapted to irrigation pumping.

They are operated with little expense. They require but little attention.

They enable you to utilize the waste waters such as deep streams, sloughs and ponds upon your own land.

The farmer who has a water supply of his own, so that he may irrigate a few hours now and again, without regard to whether the water is flowing in the company ditch, is the independent farmer.

A reservoir on your own land and an I. H. C. gasoline engine to give you the water when you want it, where you want it, is the solution of the problem.

The I. H. C. gasoline engine can be used for other purposes beside pumping. It is a general purpose engine, which will be found an all around handy farm helper—to run grinder, sheller, separator, fanning mill, washing machine, churn, grindstone, etc. The I.H.C. line includes besides Famous pumping engines and jacks, the following:

Stationary engines, from 1 to 25 horse-power; Portable engines, from 2 to 20 horse-power; Skidded engines, from 2 to 8-horse-power; Tractors, 12, 15 and 20-horse-power, and Sawing and Spraying outfits.

Call on the International local agent for catalogs and all particulars in regard to these engines, or write nearest branch house.

TREE TANGLEFOOT

A Sticky Preparation Applied Directly to the Bark of the Trees

Will not injure trees. A band 5 inches wide and 1-16-inch thick cannot be crossed by any climbing insect pest. Remains sticky five to ten times as long as any other known substance. You can test it at slight expense, as no apparatus is required. Used by the carload in New England against the Gypsy and Brown-Tail moths. In California it preserves prune orchards from the Canker Worm. Wherever the Gypsy or Brown-tail Moths, Tussock Moths, Fall or Spring Canker Worm or Web Worm appear TREE TANGLEFOOT is of great value, and should be used when the caterpillars begin to crawl while they are very young.

Price, 1-lb. cans, 30c; 3-lb. cans, 85c; 10-lb. cans, $2.65; 20-lb. cans, $4.80. The only safe and effective banding preparation. Send for testimonials.

Deciduous Fruit Culture

By J. W. Mills

ALMOND CULTURE.

Almond culture is one branch of fruit growing in California that has never been overdone. The question is often asked us, "is almond growing profitable?" No doubt it is in some localities. There are few localities however where they can be safely grown. After blooming time they will not stand any frost whatever. We have seen almonds killed when nearly full grown, the trees in full leaf and apparently past all danger from frost. The trees were beginning to sag under the weight of the fruit and a full crop seemed assured. Young oranges the size of peas in adjoining rows were uninjured and even the tender succulent growth on the ends of the almond and orange trees showed not the least sign of frost injury. The almond nuts did not show any injury for several days, when they commenced to drop, and investigation showed a slight discoloration of the jelly-like substance that develops into the fruit. There were about thirty trees representing seventeen varieties, with nuts in various stages of development, from the size of a pea to nearly grown almonds. There promised to be a record crop of nuts, but less than a peck stayed on the trees. Within two weeks they were all on the ground.

There may be localities where late frosts never occur and other conditions are favorable to the growth and maturity of the almond, but we have never located them with assurance that they will hold the record for several succeeding years. There is a district in the west end of Antelope Valley which I investigated one time, and while the finished product was unexcelled, the result for that season showed an average of three-fourths of a pound of nuts per tree. The trees were twelve to fifteen years old, but a dry season and frost cut down the product. March 2nd showed that one-third of the bloom was out. On March 19th the thermometer got down to 28 degrees; April 3rd to 13th it occasionally struck 30 degrees and 32 degrees. On March 10th the trees were in full bloom. These conditions were not usual, but they do occur, showing that the most favored spots are occasionally out of the race.

There is a small almond orchard adjoining the government date garden at Indio, which is now in bearing. This is its third bearing season, and being of the Jordan variety should be a good test as it is an early blooming variety.

A locality in which frosts occur but once in four or five years after the middle of February, should be well adapted to growing almonds. This applies to sections outside of the desert. There is no possible way to ascertain where such places exist except by actual experimentation. It is a fact that one particular place will be visited sometimes by frost, while one near by will suffer severely at another time.

For this reason almond growing is an uncertain venture. Statistics show that there is considerably less acreage devoted to almond growing in California than there was a number of years ago. This is due to the uncertainty of getting a crop.

There are many fruit crops that give each year an income that can be relied upon, which is more satisfactory to most people, even though they do not average up with almonds.

There were in Sutter county many years ago, two old almond orchards on adjoining ranches; one was on an elevation which answered all the requirements of an ideal situation. The trees were carefully cultivated and given all the care necessary to make them thrifty and appear well.

The other orchard was on lower ground used as a pasture for many years, while the first named orchard was being cultivated. The almond orchard used as a pasture was sown to alfalfa, which resulted in a poor stand, and the trees being more or less injured by stock, while young, made a poor stand of both trees and alfalfa. The result was that when the trees became old, they had plenty of room and grew large and bore well. This orchard produced on an average $100 per acre in nuts, while the other orchard paid much less.

The lesson we drew from this was, that too many of our almond orchards are planted too close, and while the orchard we have in mind was handicapped by neglect, the ample room given the trees more than made up for this.

The great majority of almond groves which have reached the age of twelve to twenty years, have their branches either shooting up into the sky or interlocked with adjoining trees. This fault may have as much to do with lowering the returns from almond culture as occasional late frosts in favorable localities.

It is now a settled fact that better results are obtained when two or more varieties are planted in close proximity. Ne Plus Ultra, I X L, and Golden State are three of the best commercial varieties. Hard-shells also pay well even though the price is but half.

Two rows of each variety planted alternately in an orchard will insure all the benefit obtainable from cross pollination. The trees should be planted not less than 30 feet apart each way. When they are fifteen or twenty years old they will nearly meet at 35 feet. It may be practical to grow peaches in the center of the squares when planting 30 to 35 feet apart and at the end of eight or ten years they should be removed; during this period the peaches will produce several good crops. Berries or alfalfa would perhaps be better, but irrigation would have to be practiced in that case. Any rich sandy loam is suitable for almond growing.

Almond trees come into bearing at three to four years, but profitable crops cannot be expected under five or six years. Paper shells produce six to twenty pounds per tree at this age, while hard shells produce two or three times that amount.—J. W. Mills.

The unversed cannot tell much about the speed of birds or insects. The cormorant seems to fly slowly, yet it travels about a mile a minute, while the bee, which appears to be going like a bullet, only goes a mile in two minutes. Many sportsmen think a quail flies faster than a duck, but it does not.

PRUNING THE APPLE TREE.

THE apple is the most cosmopolitan of orchard fruits and the one about which there seems to be more varied opinions in regard to the pruning of it. Every apple grower is confronted every winter with the question of how best to prune his trees. While pruning is a natural process it should be avoided as much as possible as the tree gets older. The heaviest pruning, in proportion to the amount of tree top, is done during the first two or three years of the tree's growth. During this time the apple tree should be properly started and should be well pruned so that when it comes into bearing it will not be necessary to prune it severely.

Two forms are generally considered in the starting of the young apple tree in the orchard, the low and high headed tree. The choice of either one of these forms depends, to great extent, on the cultural methods to be followed by the orchardist, and upon the climatic conditions. The high headed tree is perhaps better suited for northern and eastern conditions while the low headed tree is better adapted to our section of the country.

The first pruning of the young apple tree, after it has been transplanted to the apple orchard, should be carefully done as at this time we determine the height of the trunk. The top should be cut back to about twenty-four inches from the ground. The following spring a number of limbs will develop from the trunk. Three to five limbs only should be allowed to form the scaffold. At the next pruning, the following spring, these scaffold limbs are again cut back somewhat and any interfering limbs are also removed. At the third and even the fourth pruning the limbs should be cut back and the tree rounded generally. By this method of pruning the tree is shaped up and it may be properly started.

While there are some fruit growers who claim that the bearing apple tree should be cut back every year the nature of the growth at that time in this climate does not warrant such practice and on the whole the results are not so satisfactory. The bearing tree should be pruned as lightly as possible. It does not produce the same rank growth that the young tree does during the first few years. A great deal of the vitality of the bearing tree is used up in the production of the fruit, and in fruit spores for the following crop. While the tree does not require severe pruning it should be pruned a little every year. All the dead and broken limbs should be removed as well as those which interfere. Avoid the cutting of large branches.

The limbs should be cut as near the trunk as possible so the wound may heal over quickly. Never cut limbs so as to leave a stump one or more inches in length. Such stumps if left never heal over. The healing of the wound depends on the activity of the cambium layer. This layer is most active in the spring after the tree starts to growing. The longer the wound remains exposed the more it will dry and crack. Wounds which are made in the fall or mid-winter necessarily remain longer before the cambium layer begins to grow over them than those made in the spring just before the tree starts to growing. While trees can and may be pruned any time during their dormant period—that is during the fall, winter, and spring—the preferable time is in the spring, shortly before growth begins. —Fabian Garcia of New Mexico Ex. Sta.

BUDDING GRAPE VINES.

IT is quite often desirable to work over the tops of vines without cutting off the well formed crown. In 1888 budding in one-year-old canes was successfully done, one grower stating that he had practiced the method a number of times, and seldom, if ever lost a bud. He saved the canes of the variety desired at pruning time and when the sap was flowing freely in the spring, he budded just as he would peach, plum or any other nursery stock.

Herbaceous budding is another method of changing the variety of grapes without sacrificing the top. The vines are pruned in the usual way and at a certain stage of growth of the young shoots, buds are inserted and tied in just as in ordinary budding. There is a certain stage of growth when the new shoots can be slightly bent without snapping in two. An incision is made lengthwise in the cane, about an inch and a half long and by bending that part of the cane inward, the bark separates and bulges outward. A bud, cut in the usual way, is inserted while the cane is so bent as to cause the bark to bulge. When the bud is inserted and the branch released, the bark will resume its former position, excepting that it is now pressing down on the bud and holding it firmly in place. Wrapping with waxed cloth, or twine, will serve to seal up the incision so as to exclude the air. Unwaxed twine or cloth will serve the purpose, but its use requires more time. Vines budded in this way will, if carefully done, be quickly and satisfactorily converted into any variety desired.

There is a certain method of making the bud that must be observed. It should be taken from growth of about the same maturity as the stock into which it is inserted. The stem of the leaf at the bud, together with part of the leaf about the size of a nickle or a twenty-five cent piece, should be left on the end of bud. The bud, with this leaf stalk with its leaf trimmed to the size described, is inserted as told above. In a few days the leaf stalk will indicate by its color and texture whether it will grow or fail. If it makes a union and grows, the leaf stalk will proceed to ripen and soon drop out in a clean cut manner. If no union takes place, the leaf stalk of the inserted bud will shrivel, turn dark and stick to the bud.

About two weeks after the budding is done the wrapping should be cut on the side opposite the buds. As soon as the union is well grown over, cut the canes off about two buds beyond the inserted one. As soon as that makes a good start the canes may be trimmed up to them or they may be left till next prunning time.

NUT GRAPE JELLY.

Dissolve one-half package of gelatin in cup of water, pour same into one pint of boiling grape juice sweetened to taste. When half congealed stir in 5 cents' worth of shelled walnuts, then pour in mold and set in cold place till fully congealed. Serve with whipped cream.

"I keep all papers that are worth keeping and in after years find them valuable. A friend sent four miles for a copy of an old paper. I looked in my garret and found it at once."

Small Fruits and Vegetables

THE RUNNING OUT OF SPUDS.

FEW PLANTS under cultivation are more susceptible to variation than the potato. The more a plant varies the greater is the chance for improvement with proper methods of selection and also a corresponding tendency to deteriorate when poor methods are practiced. We are all interested in the improvement of our potatoes. This has been brought about from the fact that we frequently get a variety that gives good satisfaction for a few years and then the yield decreases and the tubers lose their uniform appearance. Almost as many theories are advanced for this running out and remedies given as there are growers. A few of the remedies given are: Plant when the moon is right, always plant large tubers, never plant seed ends, always leave one or two eyes to a piece as the case may be, exchange seed, etc.

None of these remedies will prevent varieties from running out. The changing of seed may be beneficial, provided the person from whom the seed is gotten practices good methods of selection. The benefit derived is not from the mere fact that the seed is changed from one farm to another. Varieties run out when the seed is not properly selected from year to year. The place to select seed is in the field. If the variety is a good one any farmer with the proper knowledge can maintain its productiveness and quality with comparatively little time and expense and a careful farmer can increase its productiveness and improve its quality. As we dig potatoes or look at them in the bin we must note the remarkable lack of similarity or the tendency to vary that is exhibited.

It is a noticeable fact that some hills will have a large number of tubers, uniform in size and shape while other hills grown under the same conditions will have a few ill-shaped tubers or one large tuber and a few small ones. A tuber from vigorous productive plants although it may be the only small one in the hill, because it started late and did not have time to develop full size, will possess and transmit the characteristics of its worthy parent. So also the only large tuber from the poor hill in which it alone attained marketable size will transmit the tendencies of the hill. We see then that inspection of the individual tubers alone will not enable us to judge whether they are desirable for seed or not, but the whole hill must be examined.

The unit for selection is the plant and therefore the place to select potatoes for seed is in the field, where the whole plant can be examined. In 1907 we planted two patches each of twelve varieties of potatoes. One of each variety was planted with the large and small seed selected from the best hills. The other was planted with seed selected from medium to poor hills. As near as it was possible the two patches of each variety had the same kind of soil and treatment. The results were interesting. The average yield of the field planted with tubers from medium to poor hills was 6,100 pounds. The average yield of that planted with tubers from the good hills was 8100 pounds or a gain of twenty sacks to the acre. The crop from the good hills was not only larger but the tubers were more uniform in size and appearance than those from the medium to poor hills. —Denver Field and Farm.

RAISING CUCUMBERS FOR PROFIT

The earlier cucumbers can be marketed the greater the profit to the grower, says an Eastern writer. In fact there is seldom any profit in late ones. To get them early the plants must be started in hot houses or hot beds. Nearly all growers use hot beds heated by fire. They are usually five feet nine inches wide, and they can be made any length up to 200 feet. But a bed seventy-five or eighty feet long will prove more satisfactory than one of greater length, because it can be heated more uniformly and with less fuel.

It is important to have the hot bed on a sheltered spot with a sunny exposure, and there should be slope enough to insure a good draught in the flues. The furnace, or fire box, must be at the lower end, and outside of the bed. Two flues are necessary to heat the bed. They should be five inches from the sides, and extend from the furnace to the upper end of the bed where they terminate in chimneys six or eight feet high. The flues are simply trenches with sloping sides ten or twelve inches deep, and covered with flat stones. The dirt over the flues should be thirty-six inches deep at the furnace, and taper down to about eight inches at the upper end, in a bed eighty feet long. Some time before the bed is to be used it should be covered with two or three inches of well-rotted manure and this should be worked in, and the surface thoroughly fined just before the seeds are planted.

The seeds are planted in dirt bands. These dirt bands are bottomless boxes made of thin strips of veneering four inches square and three inches deep. They are placed snugly in the bed without tacking and filled with good loamy soil from the woods. The soil in the boxes is firmed down before the seeds are put in. If the seeds are good, three in a box are plenty. The soil should be screened for covering the seed, and care should be taken not to cover them too deep. It is important to have the bed well warmed up before the planting is done. If conditions are favorable the plants will be up in three or four days.

Success in growing cucumbers depends much upon the selection of the soil. They must have a loose, loamy soil with an abundance of humus in it. It is useless to plant them on a compact clay soil. The ideal cucumber land is a sheltered valley protected from the northwest winds, and having a southeast exposure. From such land heavily manured and properly prepared and cultivated a prodigious yield of early cucumbers can be obtained.

The land should be plowed in the fall and a heavy coat of manure worked in with a disk. Thirty tons to the acre are about right. Plow the land again in the spring as soon as the ground is dry enough, and harrow thoroughly. Mark off the rows four feet apart each way, and put a forkful of well-rotted manure in each hill, and cover it with two furrows with a one-horse turning plow. The hills are then opened up, the manure well mixed with the soil, and the plants put in. If the plants are properly wetted down in the bed, and carefully handled and properly set out, they will hardly stop growing.

Start the cultivator as soon as the plants are all in the field, and keep it going till the vines interfere. Cultivate deep and close to the plants until they start to run. After that keep away and run the cultivator shallow so as not to mutilate the roots.

The Ornamental Garden

COMMERCIAL BULB GROWING.

THE following paper was read at the Pacific Coast Nurserymen's Association meeting recently by A. Lingham, a nurseryman at Puyallup, Wash.:

It is usual for a man while carrying on his regular business to seek some relaxations from the daily routine. He becomes interested in some scientific problem or branch of work entirely outside his own profession, in which he finds rest and recreation. So he leaves the main track for a run over the branch line, landing among his favorite haunts cultivating a hobby.

A nurseryman seldom has much idle time on his hands; but we often find him raising fancy chickens, conducting a dairy farm, or cultivating some special crop, not listed in his catalogue, just to keep him busy.

My little hobby has been growing bulbs, and they have had a special interest for me, ever since I went rambling over the foothills and valleys in search of the wild ones.

The alluvial soil of our valleys and river bottoms, having natural drainage and plenty of available moisture, furnishes the ideal conditions for growing bulbs and the crop is as certain as producing ordinary vegetables. Hyacinths and tulips are grown equal to the best imported bulbs.

The large bulb farms in Holland contain as high as forty acres, and within the next ten or twenty years we ought to have a few of this size in operation along this coast; in fact, as recently published in the Horticulturist, a company is already organized in Whatcom county, Washington, to start a forty-acre bulb farm, and we trust that Mr. George Gibbs and his partner will meet with every success in their new venture.

This coming industry has long passed its experimental stage, and the high-grade bulbs producing their fancy flower spikes form the best argument in its behalf.

Hyacinths and tulips we plant in October for best results, and the crop is ready for harvest the following June. Crocus are planted fully a month earlier as these naturally blossome and mature quite early. Tulips increase three to one on an average. There is the No. 1 large flowering bulb, the No. 2 size for planting out again, and the No. 3 or small bulb, which requires two years' growth to form the large fancy bulb. Our experience with hyacinth bulbs is that they grow larger and more solid each year where conditions are favorable, The large bulbs we use for propagating and cut them to make them multiply. We planted some young bulbels one-fourth inch in diameter last fall; in digging them this summer they measured one to one and a half inches in diameter, smooth, round bulbs.

In Holland I believe the bulbs are planted in uniform beds of four feet wide, with the rows six and eight inches apart, and walks eighteen inches between beds. This system requires cultivating by hand entirely, or some method of mulching to keep down the weeds. Women and children are largely employed on the bulb farms, and work for small wages. Ten rows of crocus bulbs are planted in a four-foot bed, which is not leaving much room for cultivation.

We plant hyacinths and tulips in rows eighteen inches apart and the crocus one foot between rows, using wheel hoes and cultivators to give clean cultivation through the growing season.

For commercial planting it might be more profitable to keep the rows about two and a half feet apart or wide enough to admit of cultivating by horse, and materially lessen the expense of so much hand labor.

When storing bulbs away we first remove the stems and old loose skins, then place in flats or shallow boxes about three inches deep, piling them crosswise in a cool ventilated shed or store room. This preserves the rich chestnut brown color on the tulips and keeps hyacinths and other bulbs plump and sound till fall planting time.

Millions of bulbs are imported each year with the demand steadily increasing, and varieties that have been cultivated for over three hundred years are still as good today.

When we consider the natural adaptability of our soil and climatic conditions to their culture, we have every reason to look on this as one of our important industries, and when we have furnished the supply for the United States we might grow some for export instead of importing our supply from Europe as in the past.

OVER POTTING OF PLANTS.

Many persons make the mistake of setting small house plants in pots that are too large for them. These large pots require more window space than would be needed for smaller ones, and with some kinds of plants it tends to lessen the amount of bloom. There appears to be a sort of instinct in many plants that prompts them to put forth their best efforts to reproduce themselves when their environment does not seem conducive to their own long life. And as nature's way for most plants to reproduce themselves is by seed, and seed is produced only in the flower, a show of bloom is made by the plants when the roots are somewhat crowded and the supply of soil not too great. Most experienced florists claim that the best method is that of repotting plants into larger pots only as they actually need the increased space. The right time to move a plant from a small to a larger pot is shown by the roots beginning to mat around the outside of the ball of earth next to the edge of the pot. The ball of earth may easily be removed from a pot by turning the pot upside down and tapping it slightly on the edge of a table. Be sure and provide for good drainage in the new pot by putting a few pieces of broken porous crockery (small pieces of broken flower pot answer admirably) in the bottom.

The Japanese morning glory is quite a gorgeous plant, its vines attaining a height of thirty to forty feet in a short while and making a dense, luxuriant screen of foliage that is variously mottled. A chief attraction about this plant is the size and coloring of the flowers. They grow four to five inches across and include all colors and combinations from deep velvety purple to the daintiest blue, from snow-white to soft rose, through all the shades of crimson and red to rich garnet. Some of the blossoms are rich deep shades and others are of the most delicate tints. There are also solid velvety colors, while others are mottled and spotted. Blooms are furnished in profusion and the plant is quite desirable for porch planting.

Irrigation and Forestry

ABOUT IRRIGATION.

THE ownership of water for irrigation is as important to the farmer as the ownership of the land. In arid countries the water is often the most valuable of the two elements, land that is practically without value being made valuable by the application of water. It frequently happens where the water supply is limited that lands for which water is available has a high value while adjoining lands of exactly similar character are practically worthless. This being true, it is readily apparent that the ownership of water is at least equally important with ownership of land, and that the ideal condition, from the standpoint of the farmer, is the ownership by himself of both.

In the broad sense the community at large has an interest in both the land and the water that is superior to that of the individual owner, whoever he may be, but the present civilization regards private ownership of the agricultural lands by men who live upon and till them as the best method of conserving the public interest and promoting the public welfare. Land laws of the United States have been from the beginning designed to place the lands in the hands of men who would use them. This purpose has not always been achieved. There have been bad laws as well as good; but it will probably be conceded that the American people as a whole have desired the enactment of laws that would facilitate the acquisition of the farming lands by practical farmers. This is the correct attitude. It is eminently right and proper that the man who tills and lives upon the soil should have his tenure assured.

Our attitude toward water necessary to irrigation and used for irrigation should be the same, but unfortunately it has not been the same. Early settlement in this country was in those sections where rainfall is abundant; when the march of civilization reached the arid lands the conditions encountered were new. A people to whom the ownership of land had been all important very naturally continued to so consider it, with the result that all too little thought was given to the ownership of water. The diversion or distribution of flowing water in considerable quantities calls for large investment, in labor and machinery, in dams, dikes, and canals, and water laws were so framed as to encourage the investment of capital in irrigation systems as a distinct enterprise. To a very large extent it is still so regarded; but there is a growing appreciation of the fact that the ownership of water is not less important to the farmer than the ownership of land, and a strong tendency to develop irrigation systems under conditions that provide for and insure their ownership in common.

The ideal system of water ownership is that which makes the water forever appurtenant to the land. The ideal water development is that in which the costs are borne by the land. The best attribute of farm life in America is the independence of the farmer. In the humid states ownership of the land he farms is sufficient to this end. In the arid states the ownership of both the land and the water is essential to real independence. Ownership of the water supply in an arid country is more important than ownership of the land because without the water the land has little or no value. Every evil that attaches to a system of landlordism and tenantry may attach to divided ownership of lands and of water used for their irrigation. Every advantage which the farmer obtains is from ownership of the water with which he irrigates.

This is a matter of vast importance to the people of the United States, for it bears directly upon the most important problem of our national life—that of maintaining upon the soil a prosperous, independent, home-owning population. Millions of acres in the West must come under irrigation, and it is of national important that these lands be developed under conditions assuring the greatest freedom and highest standard of citizenship. The water must be appurtenant to the land.—The Great West.

WATER CODE DEMANDED.

The State Grange of Oregon adopted the following:

That it is the duty of the State of Oregon, at the earliest possible time, to codify and enact a complete, concise and definite water law, leaving to the courts only the mere interpretation of this law on such occasion as it might be brought into dispute;

That such water law should be based upon the best experience of other states and countries, such as Wyoming, Idaho and Canada, and should include the following fundamental principles:

1. That no water right should become vested except by direct grant from the state.

2. To provide a system whereby the priority and limitations of every existing right to the use of water can eventually be ascertained.

3. To provide a reliable record in some central office of all water rights as determined, and of new rights as initiated.

4. That actual measurements of ditches and streams be made as a basis for the adjudication of existing rights and the initiation of new rights to the surplus water, if any.

5. To provide a definite procedure whereby rights to such surplus water may be acquired.

6. That beneficial use should be the basis of all rights to the use of water, and that water for irrigation purposes should be made appurtenant to the land irrigated.

7. All rights to the use of water for power development should be limited to a period of 25 years, subject to renewal under certain restrictions.

8. To provide an efficient administrative system, with proper officers, for the distribution of the water supply among those entitled to its use.

Forest Supervisor C. H. Shinn has issued a schedule for prices and time for pasturage of cattle on the National forests for next season. Prices for cattle will be 30 cents, horses 40, and they will be pastured from June 1st to October 31st, or a year-long fee may be paid of 50 cents per head on cattle and 70 cents per head on horses.

Sonoma Pomona Grange held its last regular meeting at Petaluma.

Live Stock and Dairy

Dairymen and stockmen are requested to write of their experience. Mrs. Sherman is always willing to answer queries and this, with experience of other workers, will make this department of greater value.

By Mrs. Minna E. Sherman

SWINE.

THE use of improved varieties of hogs for the increased weight on the same amount of food at the same age makes it pay well. This weight is gained almost from the start so that the six months old pigs are larger, being both thicker, taller and longer than the pigs from the common sows down in the pens today. There are some sows in the pens that are two and three generations from the common stock and in even their pigs the difference shows up strong. It is not necessary to examine the ear markings to tell the well bred ones, as they have come through this wet winter in fatter condition than the others. A trio of pure bred pigs may be purchased at reasonable prices and should be used as the basis of the business. I have often sold the boar at two years of age for the price paid for a trio at a couple of months old. There are many people who will not use full blooded sows as they claim they do not produce as large litters as the common sows. This is, no doubt, a fault that must be eliminated by selection of the best producers among the well bred sows as among the common ones. It has to be watched for in all classes of stock as well as in pigs.

Care.

The sows that dropped litters of pigs last fall should be separated from them and put by themselves. The youngsters can rustle for themselves on the grass, and the sows should have a little better feeding; some alfalfa hay with a little meal to add flesh to them, before they drop their spring pigs, will not be amiss. Every sow that is any good will nurse herself thin and if she starts in to suckle a new litter of pigs while in poor flesh the pigs will not thrive well. A check in growth in a pig's life is fatal to profits. A stunted colt will make a saddle pony, while a stunted cow will still give some milk; yet a stunted pig is a clear loss in pounds of pork. If we only desired to make the sows fat, corn alone would be good feed, but we desire bone and muscle in the coming pigs and therefore the protein of alfalfa hay or green alfalfa is most profitable feed for this purpose.

Selection.

After the sow has raised her pigs, the best of the young sows should be selected to make up the young breeding string, a few new ones being added of each fall's litter to keep up the breeding pens. On the ranch we use the pigs to eat while they are small, at about forty pounds weight. This is a cheaper source of meat supply than to feed them longer into large hogs.

A few, usually about twenty, are selected to be held for pork and hams. This lot are put into a separate place and receive growing rations all summer, until the grapes come, and then are finished off on grapes, pumpkins and corn. In California the extent of the farming blinds the eyes to the little things, yet every dollar we can keep at home saves the spending of money and makes it profitable in the end. When we learn on the ranches to count the savings possible to make, we can decrease our bills at the stores 50 per cent and yet be more healthily fed. The meat supply of the ranch can come largely from it by having a few common cows and vealing their offspring for meat. A few sheep can also be purchased and used to eat. The farmer on a large place who does not supply his table largely with home grown meats and vegetables makes a mistake.

Feeding the Sows.

After the sow farrows, give her plenty of fresh water, but no food for the first day. Then begin to feed her on bran slop made with skim milk if there is milk; if there is no milk, then use water. After a few days give her alfalfa hay or green cut alfalfa and a mixture of oil cake meal and bran in skim milk. Let her have an outside run if the days are sunny, for there is nothing like sunshine for babies of every sort. The sow that brings large litters of strong pigs should be kept and the young sows from her big litters should be ear marked; and from them, at six months old, the best should be saved for the next lot of sows. This is breeding away from sterility. Never keep, for a brood sow, a young sow from a litter that was small or weak, without you desire to run the pigs out of existence. Where there are registered pigs, I always ask how many pigs were in the litter the boar comes from; if the seller cannot tell by his books, I go elsewhere to purchase. That is as important a fact to know as it is to know that the animal is pure breed.

Pigs.

As soon as the pigs will eat, fix up a little trough in a small pen with a door too small to allow the sow to go in at. Have the trough broad, not V shaped, and keep it filled with dry bran and oil meal for the little ones to eat at, when they fancy they would like a nip. The size of the litter may be reduced rapidly by cultivating a market for suckling pigs. These sell readily at $1.50 each, dressed, to the hotels in the towns. They usually weigh from eight to twelve pounds and can be taken into town on Saturday evening. The ranch boys welcome the chance to get off early for this job on the delivery wagon.

The sow whose litters have proven small or weak is taken from the bunch and put with the fattening hogs. She will not make particularly good hams, but she will make lard and a great quantity of it. This pays well, for if one has more lard than they can use, the town people will pay a cent more a pound for fresh ranch lard in neat ten pound pails with the ranch name on it, than for the ordinary packers' lard. The hotels, too, take it in the large fifty pound cans, sending their own cans, and paying for the lard put into them. This is the best way to clean up the unprofitable sows as well as a small portion of the hogs fattened for pork. However, this is done only when the home supply has first been looked after. The success in farming is in selling well the surplus, not the things that can be used as well at home. Whenever we begin

100% A YFAR FOR TWENTY YEARS TO COW OWNERS

That's the marvelously good investment that more than ONE MILLION satisfied users are finding the

De Laval Cream Separator

With three or more cows a DE LAVAL separator saves its cost the first year, in more and better product, and it may be depended upon to go on doing so for twenty years, as there are already thousands of instances to prove.

There's half this much saving in the use of a DE LAVAL over inferior separators, while other separators last but from six months to five years instead of twenty years. They lose half that might be saved while they do last.

That's the whole separator story in a "nut shell" and the reason for the now nearly universal sale of DE LAVAL separators.

A DE LAVAL catalogue may be had for the asking. Likewise the trial of a DE LAVAL machine.

Live Oaks Farm

Frank A. Meacham, Proprietor.
Importer and breeder of RED POLLED CATTLE, SHROPSHIRE SHEEP, RAMBOUILLET SHEEP, HORNLESS AMERICAN MERINO SHEEP. Both sexes for sale. Take electric car at Petaluma or Santa Rosa for LIVE OAKS STATION. Address all mail to
Petaluma, Sonoma Co., Cal.

to buy the simple things, we have to pay, not only for the goods, but for the frills with which the trade embellishes the goods. When we buy a carton of any sort of food, we pay for the carton the high price of the goods it contains. A box of candy at fifty cents a pound is weighed to us in the paper box. While these are but trifles and we would rather have our food handled in paper and boxes on the score of cleanliness, yet we pay high prices for the package that in home produced goods we do not have to pay for at all.—M. E. Sherman.

SOME GOOD HORSE REMEDIES.

At the present high price of horses it pays to take the best care of them. Veterinary surgeons are to be commended in most towns, even if quite small, nowadays and as a general rule it pays whenever a horse is taken sick to invoke their professional aid. At the same time there are occasions when it is not possible to secure the assistance of the practitioner just at the moment it is wanted and therefore it pays to keep on the shelf in the stable a small line of standard remedies which may be administered easily and without danger or injury. Sedulous care should, however, always be exercised to keep such remedies from the reach of prying children. Harmless though veterinary remedies may be in their proper connection, they make poor playthings for the little ones.

More deaths among horses are caused by maladies of which colic is seemingly the outward appearance than by any other disease to which the horse is heir. In cases of true colic remedies are both simple and easily given, but the trouble is that what seems to be only a plain belly-ache may be due to some much more serious malady. Impaction of the bowels, inflammation and other affections may have to be dealt with and when a horse gets down and shows that he has severe pain the best thing to do is to send for the veterinarian at once. A safe remedy which may be kept on the shelf and administered in all cases of colic is as follows: Turpentine one ounce; cannabis indica one-half ounce; alcohol four ounces; and water one pint. Give as one dose pending the veterinarian's arrival. Another colic medicine which may be kept on hand is thus put up; Laudanum, one ounce; spirits nitre, one ounce; ether, one ounce; whisky, four ounces; and raw linseed oil, eight ounces. A practitioner once told us that he had most excellent success with this remedy. Another with which we have obtained successful recoveries in cases of spasmodic colic, consists of raw linseed oil, one and one-half pints; sulphuric ether, two ounces; laudanum, one ounce—to be given as one dose and repeated in two hours if necessary. It should never be forgotten that colic is superintended by indigestion and that some treatment that will remove the cause is necessary as well as that which will stop the pain and struggling.

Perhaps the next commonest ailments that fall to be dealt with continually on the farm are wounds of various sorts. When they are deeply punctured as when caused by snags, for instance, they should be probed and cared for by the veterinarian. When jagged it never pays to sew them up because the ragged places will slough anyway. In simple wounds where the cut is clean the severity of the injury will decide, of course, whether sutures (stitches) are necessary. In just plain ordinary slight wounds the best dressing is composed of a teaspoonful of pure carbolic acid to a quart of water—to be applied as a dressing. Do not wash the wound continually with soap and water. This is a very simple and cheap remedy which is available at all times. In cases where sores have festered and need cleaning out the best thing to use is peroxide of hydrogen diluted with an equal volume of plain water. This being injected into a sore secreting pus will cause the wound to foam and the injection should be continued until the foaming ceases. An excellent healing ointment is composed of oxide of zinc, one ounce; glycerine, two ounces, mixed.—Farmers, Tribune.

SORGHUM FOR SILAGE.

Sorghum has not generally been considered as satisfactory as corn for silage. Professor Plumb, of Ohio State University, states that "sorghum is not so nutritious as Indian corn. The stalks are more dense and the silage is not relished quite as well by cattle as that from corn."

In experiments at the Tennessee Station, however, A. M. Soule found that "as fine a quality of silage can be made from sorghum as from any other crop and there seems to be little choice between the feeding values of sorghum and corn silage for beef production." He states that "farmers who experience difficulty in making good silage either cut the crop too green or else have improperly constructed silos."

In the Tennessee experiments the cost of growing an acre of sorghum silage was 19.48, of corn $14.92, corn and sorghum $19.14, soy beans $19.86, but the average cost of a ton of silage from sorghum was $1.41, from corn $2, from corn and sorghum $1.86, and

from soy beans $2.83, the higher yield per acre of the sorghum accounting for the lower cost per ton.

Sorghum planted as a "second crop" will not yield more than 8 to 9 tons per acre, whereas if planted as a first crop it will yield from 12 to 20 tons per acre. The lowest cost per ton from a first crop was $1.15 and the highest $1.78; from a second crop the cost was about $2.80.

In the Tennessee experiments Red Head was found to be one of the best varieties for silage purposes. Grown with Virginia ensilage corn a very satisfactory combination for silage was obtained. "Combining these crops makes a better quality of silage, increases the yield, and reduces the cost per ton as compared with corn alone. * * * Corn and sorghum can be combined so that the resulting silage will consist of about equal percentages of each crop."

Sorghum, like corn, contains an excess of carbohydrates and is somewhat deficient in protein. It was found at the Tennessee Station that this could be corrected in a very satisfactory way, and a better balanced silage obtained by growing cowpears and other leguminous crops with the sorghum and ensiling the two together.

In experiments at the Illinois Station it was found that while "in Illinois corn seems to be the best single crop for the silo * * * under average conditions a larger tonnage of feed can usually be obtained per acre by combining corn, sorghum, and cowpeas or soy beans, but even with this combination the greater part of the crop should be corn."

In comparative tests of different crops for silage at the Kansas Station "cane and Kaffir corn gave the largest yields and lowest cost per ton of any of the annual crops, while corn ranked second, and cowpeas third."

The need for forage crops which will give large yields of good forage is becoming more pressing in the South as the raising of live stock increases. J. M. Scott, of the Florida Station, says that the value of sorghum for this purpose has not yet been fully realized. He finds that sorghum may be grown in all parts of Florida when cultivated and fertilized in practically the same way as corn. It seems to be the best and most productive silage crop that can be grown in Florida. Yields as high as 19 tons per acre were obtained. In the Florida experiments sorghum produced silage richer in total digestible nutrients and gave a larger yield of green forage per acre than corn, thus making it "not only the best crop for the silo, but also the cheapest."

It seems comparatively simple to secure a good milk supply, but experience shows that is not the case. It is a very complicated question and requires care and thought by all engaged in its handling. Cows should be provided with clean, comfortable stables and treated with kindness, and the yards should be clean and well drained.

READ THIS AND BE CONVINCED.

Tuttle's Elixir Co., Gentlemen:—We have used Tuttle's Elixir and Powders for a year or more with increasing satisfaction. They are reliable and effect a cure every time.—H. McKenna, Foreman, Mathie Brewing Co.

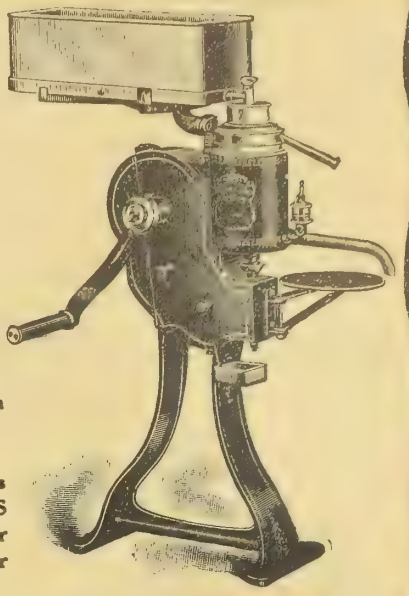
Cream Separator Frame



It is cast in one solid piece.
No bolts to shake loose.
Extreme simplicity of construction combined with great strength.
Smaller diameter of bowls.
These are some of the reasons that make the UNITED STATES CREAM SEPARATORS run easier and wear longer than any other make of Separators.

The perfect mechanical construction of the frame and the scientific construction of the separating bowl, make UNITED STATES CREAM SEPARATORS the **Cheapest Separators** on the market for any dairyman to purchase.

Other Separator frames are made of two or more pieces bolted together. The daily use soon makes the bolts become loose and the frame unsteady.

The United States holds the **World's Record** for most **perfect skimming.** This record was made in tests with the leading Cream Separators of this Country and Europe.

No other separator can compare favorably with the UNITED STATES.

Selling agents in nearly every dairy town in the Country, if none in your town, write us and we will be pleased to quote prices. Ask for our **Catalogue No. 20** and it will be mailed to you, together with a beautiful litnographed hanger in colors.

PRESIDENT TAFT.

We are just a little bit disappointed in President Taft's inaugural address in this one point, that he dismisses agriculture with a very few words. To be sure, those words are of the right tone and we presume mean far more as to his attitude toward agriculture than more words would from many others. Furthermore, he has shown his appreciation of the importance of agriculture to the country by the reappointment of James Wilson as Secretary of Agriculture. Therefore, all told, we believe that the producers of the nation may rest perfectly secure as to the attitude which our president will observe during his administration. The few words which he does devote to agriculture are as follows:

"In the department of agriculture, the use of scientific experiments on a large scale, and the spread of information derived from them for the improvement of general agriculture, must go on."

On the whole it may be said that the inaugural address was most acceptable to the people of the United States as an indication of the attitude of the present administration.

ONE COMMISSIONER.

Gov. Gillette signed the bill providing that there shall be but one horticultural commissioner in each county, last Friday. The bill is to take effect immediately and changes in the commissions will be made in the counties as soon as proper provision can be made for the examination as to qualifications of the new commissioner. Each applicant who seeks the position must pass a civil service examination before a board of experts appointed by the governor. The pay will be $6 per day. Inspectors in the various districts of the county must also pass examinations and their pay will be $3.50 per day.

The passage of this bill is generally approved by fruit growers of the state. It must be admitted, however, that in some counties where the former law worked to the entire satisfaction of the horticultural interest there was some opposition to it. But in other counties where the old commission was made a mere political plum it is believed the present law will prove infinitely better.

JAMES WILSON.

The appointment of James Wilson as Secretary of Agriculture, while anticipated, has given great satisfaction and assurance to the growers of the country. Mr. Wilson has served for twelve years and has given the longest service as cabinet officer ever given by one man. He was first appointed at the beginning of the McKinley administration, and if he serves through the present Taft administration will have served sixteen years.

He was born in Ayrshire, Scotland, in 1835, and at the age of 17 was brought to this country by his parents. He was educated in the public schools of Iowa and at Iowa college. He engaged in farming, and, entering state politics, was a member of the twelfth, thirteenth and fourteenth assemblies of Iowa, being elected speaker of the assembly in his last term. He served three terms in congress.

In the forty-eighth congress his seat was contested, and the opponents of General Grant, who was then nearing his end at Mount McGregor, used the seating contest for a filibuster to defeat the Grant retirement bill. Mr. Wilson saved the measure by resigning, on the stipulation that the Grant bill should be immediately passed.

POSTAL PROGRESS.

California is entertaining this week Mr. Frederick Converse Beach, editor of the Scientific American and President of the American Postal Progress League. It is hoped by the friends of the parcels post that the visit of Mr. Beach will aid in creating a new interest on this coast for this needed reform in our postal service. The endorsement by President Roosevelt in his special message to Congress of the parcels post was so emphatic that it has given a position and an impetus to this movement which will give it greater advancement than it has had heretofore.

Arrangements have been made for a meeting to be held in the Chamber of Commerce rooms, Los Angeles, next Monday afternoon at 2:30 to discuss parcels post and its relation to the interests of our country. Mr. Edward Berwick, President of the State league will preside and addresses will be made by Mr. Beach and by President Booth of the Los Angeles Chamber of Commerce.

JASTRO FOR PRESIDENT.

The directors of the State Agricultural Society which recently met in Sacramento, elected one of the strong men of the state to act as president of the association for the coming year. He is Mr. H. A. Jastro of Bakersfield. Mr. Jastro has also recently been re-elected to act as president for the second year of The American National Live Stock Association, in which Association, he has not only served faithfully, but most effectively. The former president was Mr. B. F. Rush who has served for the past six years. Other officers of the association are: Frank J. Burke, of San Jose, vice-president; J. A. Filcher, secretary; L. R. Miller, assistant secretary; California National Bank, treasurer. C. W. Payne will be superintendent of Race Track and Live Stock departments while Fred R. Martin will be in charge of the officers and exhibits.

It is reported that the new pavillion will be completed in time for this year's fair, which will be held August 28 to September 4. The fair has been working toward a more representative institution of our state than it was some years ago, but there are other opportunities for material advancement. We trust the management will this year eliminate some of the objectionable features which prevailed last year. We think that efforts towards freak events like weddings in lions' dens, locomotive collisions and such sensational features do not add dignity to a State Agricultural Meeting. We are told that such things are necessary in order to draw the crowd and make the fair self-supporting. If such be the case, it is time the farmers of the state realized it and permitted the association to die. We cannot believe such is the case.

True there can be no objection to more or less fun making at such events as it is to a certain extent, a time of relaxation for many who go there, but to prostitute one of the most sacred rites which has ever been instituted by the human race, and make an exhibit of it before a gaping crowd of merrymakers, adds, as we have remarked, little dignity to such an event.

This state is worthy of a good agricultural fair in which live stock and farm products are brought to the front and made an educational factor for the farmer. The pool seller was driven away a few years ago. It ceased to be the state gambling event of the year. Let the upward tendency be encouraged and we may yet have an agricultural fair worthy the state.

HUMUS.

In the article on first page of this week's Cultivator, written by Prof. Shaw of the State University, is the statement that "Plant food and fertility are not synonymous." A soil may contain a vast amount of plant food and still be a barren desert. In other words, it is not fertile. The elements which go to make up the requirements for plant growth are all there but locked up and beyond the reach of the rootlets. The key for unlocking this fertility which will fit practically every soil is shown by the exhaustive article of Prof. Shaw to be humus. The Cultivator has spoken of this often but is glad to be again able to give another excellent article on this subject. We trust that every farmer and fruit grower will read Prof. Shaw's article closely.

DEMONSTRATION TRAIN.

The Southern Pacific Railway Company is surely doing a service for the agricultural and horticultural interests of California in conducting the special agricultural and horticultural demonstration train. President Benjamin Ide Wheeler and Professor E. J. Wickson of the State University head a large delegation of talented speakers from the staff of the Agricultural College. The initial Southern California meeting was held in Pasadena yesterday morning, the remainder of the day and today will be spent in the San Gabriel Valley. Pomona and thence on east to Riverside will be touched the remainder of the week. Monday there will be meetings at Bloomington, Colton, High Grove and Riverside; Tuesday, San Bernardino, Redlands, Crafton, Beaumont; Wednesday, Banning, Indio, Coachella; Thursday, Calexico, Heber, El Centro; Friday, Imperial, Brawley, Rockwood, Holtville; Saturday, Mecca and Thermal.

LAGUNA DAM.

We note in the news items that Laguna dam is practically completed and that the people at Yuma are prepared to commemorate the event on March 30th and 31st by a great celebration.

This work which has been taken up by the Reclamation Bureau of the United States Department of Agriculture has been under way for several years and makes possible its claim, the irrigation of 2,000,000 acres of land in Arizona and California. This dam is not built for storage but merely for the purpose of diverting the water from the river channels to the lands.

The wealth which this work will bring to a section of the country which has heretofore been an almost absolute desert is impossible to estimate.

Agricultural Notes of the Pacific Coast

Northern California

Vacaville reports promise of immense setting of practically all fruit crops.

Italians at Sunset, Sutter county, are planting heavily of garden truck this spring.

Sutter county will plant more fruit and nut trees this season than for many years.

The rainfall at Ukiah to date is 49.36 inches, more than twice as much as last year.

Davis fruit growers are appealing for a cannery to handle surplus fruit of that section.

Some peach orchards in Sutter county will be taken out to make room for alfalfa fields.

Rural delivery has been suspended in Suisun valley, Solano county, because of extremely bad roads.

One rancher at Colusa will plow up about 100 acres of hops this spring and plant the ground to sugar beets.

The fruit inspector of the orchards about Davis reports plenty of holdover blight in many of the orchards this season.

A Santa Rosa farmer is experimenting with a promising fibre plant called "Phonnium lanez," which makes a high grade twine.

Much wheat and barley in the overflowed lands along the rivers were covered so long with water as to be completely drowned out.

The long wet weather deferred the winter spraying so that every spray pump in the orchards has been kept busy since the settled weather came.

Notwithstanding early reports that the Yuba cannery would not operate during the coming season it is now definitely annouced it will be in the field for its usual amount of fruit.

Sutter and Yuba Wool-Growers Associations take exception to some of the provisions which are included in the bill now before the State Legislature regulating the sheep industry.

The more settled weather which has been given to the farmers of the Sacramento valley has put the ground in good condition so that every plow and horse in the valley is now busy.

The Assembly has passed a bill to submit to the people a constitutional amendment giving the people the right to fish along the banks of all streams, regardless of the ownership of the abutting property.

The creameries near Ferndale, Humboldt county, on their last pay day paid as follows from the different creameries for butter fat: Capital, 40; Central, 40; Cream City, 40; Eel River, 40; Ferndale, 40; Grizzly Bluff, 40; Riverside, 40; Pioneer, 38½.

The recent Congress allotted to the Chico Plant Introduction Gardens $21,380.00 for expense items the coming years, also a special appropriation of $400 to investigate the relation of wild geese to the grain crop of California.

The assemblyman from Yolo county has just introduced a bill calling for the formation of a drainage district to include Yolo, Solano, Sacramento, and Sutter counties. The idea will be to carry the water away through a large canal more than six miles long. It will cost about $150,000.

Central California

Madera is one of the newest in the Farmers Union line.

Hanford is to have an alfalfa meal factory in the near future.

Plowing has been begun in the orange groves at Tulare county.

For the first time in years, wheat is selling at $2.00 per hundred in San Joaquin Valley.

A dried fruit concern at Fresno has let a contract for a $15,000 addition to the packing house.

Orchard planting at Turlock has exhausted the stocks in most of the nurseries of that section.

It is predicted that the asparagus pack of this state will be much larger this year than heretofore.

Kerman will engage quite extensively in cantaloupe culture this year. One planter there will cultivate about 20 acres.

The Leedham Bulb Company of Santa Cruz recently shipped 24,000 daffodils to Los Angeles and San Francisco.

This year's rainfall at Watsonville has not been exceeded, since records have been kept there, but once in the past 30 years.

Exeter has been shipping many hogs to market recently, being driven in from the pasture on "mast" in fine condition.

One of the principal roadways at West Willows, Santa Clara county, has been beautified by trees furnished by Mr. H. G. Keesling.

The Mesa citrus belt country near Bakersfield will have a new subdivision of land which will be planted to oranges this season.

The increased Eastern demand for dried fruits has given a stimulus to the market and much fruit is now moving out of the producers' hands.

Many blooming almonds have been damaged by blustering rain storms which passed over the northern end of the San Joaquin Valley the last of February.

The Turlock fruit juice factory had such a successful season that an extensive addition is being made and better appliances added for handling next year's output.

Steps have been taken in the Lind say, Tulare county, section for the formation of a protective district to care for the large amount of storm water which injures much orchard property.

Ten miles of new irrigation ditches have been constructed by the Fresno Irrigation Farms Company on the lands at Kerman, and much new acreage of almonds and other crops will be planted this year.

Both the sugar factories at Visalia and Corcoran will operate this season on more than 8,000 acres of beets already planted. It is reported that the Visalia factory will run three months and the one at Corcoran two months.

A large stock farm in western Fresno county is preparing to shear sheep this year with a new power operated shearing plant, and 17 machines will be operated by one engine, and about 50,000 sheep will be shorn. The plant will handle about 150 sheep a day.

Southern California

Saticoy is shipping walnuts and oranges.

Navel oranges of Tustin will all be shipped by March 15th.

Coachella Valley asparagus sold in Chicago at $1.25 per pound.

The Mound Farmers Club held its regular meeting last Tuesday.

Cantaloupes are practically all planted in the Coachella Valley section.

Highland district shipped during the month of February 376 cars of oranges.

Large acreage will be planted to asparagus on the peat lands near Huntington Beach.

One cantaloupe grower at El Centro, Imperial Valley, has 20 acres of cants, each hill of which is covered with glass.

Richland Walnut Growers' Association recently adopted by-laws, and will be in working trim for next season's shipments.

Southern California has made the heaviest shipments of oranges during the last two weeks of any period during the past year.

Imperial recently had a slight touch of frost but said it was not sufficient to injure the young cantaloupes which are now growing nicely.

The onion pack of the Coachella Valley aggregated about 250,000 crates, and is said to be one of the best packs on the Eastern market.

The celery crop of the past year is practically all shipped. The season has been very successful, and a most excellent product has been sent to market.

Redlands and Highland are joining in a fine roadway connecting the two communities, which will be ornamented with a double row of trees the entire distance.

The president of the Orange County Celery Association says that indications are that the county will have about the same acreage of celery as last year, which was about 3000 acres.

The rangers in charge of the Forest Reserve above Pasadena have been busy for the past few weeks planting over 15,000 pine trees. They have been largely along the banks of the Arroyo Seco.

A company of Los Angeles capitalists has been organized under the title of the "Chuckawalla Land & Water Company," and it will bring water from the Colorado River to the lands of the Palo Verde Valley in Imperial county.

Walnut growers of the various associations of Southern California held a conference in Los Angeles last Thursday, to discuss plans of getting into better working condition than the walnut men have ever succeeded in securing.

Fruit growers along the banks of Santiago creek have petitioned the supervisors of Orange county to prevent the dumping of cull oranges from the packing houses into the bed of the creek, as they are washed down the stream and are liable to endanger the spread of scale to other orchards below.

The Coast

Sales of wheat have been made at Tacoma at $1.16.

Hop buyers at Portland are now offering 10½ cents.

There are about 11,000 acres of rice in the Hawaiian Islands.

About 100 acres of cantaloupes will be planted near Yuma this season.

Spokane, Washington, is now selling Malaga grapes shipped in from California points.

The sugar industry of the Hawaiian Islands is practically all in the hands of 49 different corporations.

Gov. Edwin W. Norris of Montana was chosen as president of the Trans-Missouri Dry Farming Congress.

State Fair Association of Oregon has received an appropriation of $25,000 for improving its fair grounds.

It is estimated that the wool growers of Arizona will receive half a million dollars from this year's wool clip.

The state of Washington has 166 granges with a membership of 8727. There are in the state ten Pomona granges.

About 213,000 acres of land in the Hawaiian Islands is devoted to the cultivation of sugar. Of this, 135,000 acres is under irrigation.

Seven co-operative creamery and cheese factory associations in Tillamook county, Oregon, received 14,326,111 pounds of milk during the past twelve months.

The Nevada State Legislature has passed an anti-alien bill which provides that aliens and foreigners shall be excluded from federal and state grazing lands.

The Horticultural Union, a co-operative union of fruit growers of North Yakima, Washington, has received orders for apples to be shipped to Ghent, Belgium.

Farmers near Yuma, Arizona, are planting extensively of potatoes this season. In the past that section has not raised sufficient to supply the city of Yuma alone.

The Hawaiian Islands have given much attention to storage of storm waters. The largest storage reservoir constructed to the present contains 2,500,000,000 gallons.

Ira P. Whitney, Sec. Washington State Dairy Association and Professor in the State College, is to forsake his present work and take charge of a large dairy farm in Montana.

The Antero and Lost Park Reservoir Company near Denver, Colorado, has recently established a new high line ditch which will cover a large section of new land with water.

The recent Oregon State Legislature passed an enactment which will bring into being a better system of dairying throughout the state. Three additional inspectors will be appointed to see that the provisions of the law are enforced.

The State Legislature of Oregon has been considering a bill, one of the features of which was the appointment of additional inspectors and very stringent provisions for better dairy products. This was strongly opposed by the State Dairy Association because of some unfortunate features and it has finally been defeated.

Don't Forget Quality

MIDLAND Poultry Food

Is based on ***quality*** and it is quality in Poultry Food that produces eggs. ***Cheap filler*** and ***cheap grain*** will ***not*** make eggs. ***Midland Poultry Food*** contains only the ***choicest*** cereals and animal food the market affords. Profit in the Poultry Yard

By Mrs. Frank Metcalf

We solicit short articles of a practical nature from the fancier and utility breeder, giving their experience with poultry. All inquiries pertaining to feed, management, disease and its prevention will be answered through these columns.

METHOD IN POULTRY RAISING.

The following is from an address made by Mrs. Metcalf before the Farmers' Institutes held last fall.

NO person who thinks of selfish ease can ever be trusted with the care of chickens, big or little. Their wants must not only be attended to properly, but the work must be done on time. A queer old farmer I used to know contended that farmers' boys should spend a year or two in a military school. He used to drawl, "I don't know as it would teach them to feed hogs any better, but I do know they would learn to feed them on time." And maybe a military training would be a good thing for some of us farmers' wives, in that respect and teach us to feed our chickens with more regularity, but it is scarcely feasible.

So many think the "hen business" is a trifling thing, unworthy their best endeavor. Of course they figure that they must have a few around, but look upon them as a sort of necessary nuisance, until one is set before them nicely cooked, when they wax loud in the praises thereof, and testify their appreciation by their hearty appetite, for the proof of the pudding is the eating. And did you ever see a group of farmers at the store looking sort of bored and with little to say until someone said "chicken?" What an awakening comes to that group, and how the grocer edges around that way as tale after tale of extraordinary hens crops out. The cackle and crow of the barnyard is silence compared to their gossip on this exciting subject. And why shouldn't they be animated, I'd like to know? Perhaps there are some here who think the hen is not "such a much" after all, but just listen to these few statistics and see how great she really is.

Big Business.

The annual value of market eggs and poultry in the United States is from 290 to 300 millions of dollars, actual sales, besides the great amount consumed at home and not counting the immense sums which change hands through the fancy side of the business.

Gold only brings about $90,000,000; silver $35,000,000; coal, some $200,000,000; hay $390,000,000; corn averages about $600,000,000; wheat $300,000,000 to $500,000,000; barley $30,000,000; oats $200,000,000; potatoes, $80,000,000; tobacco less than $50,000,000; so the old hen stands pretty high in the world's economy; only three products of our great country exceeding hers, namely, wheat, hay and corn. And when we consider that the greater part of this wealth is added to our coffers by the labor of farmers' wives, in addition to all our multiplicity of other cares, we feel that we are persons of importance, and we are not going to take a back seat for anyone.

Brings Independence.

The well cared for hen makes the farmer's wife independent, for she and her products bring ready money every day in the year. Sheep and cattle bring large sums at certain times, as do horses, hogs, hay and grain, but the little every-day wants count up wonderfully, and I count mine in so many chickens or so many dozens of eggs, instead of so many dollars.

On the farm I always tried to keep close account of all grain fed, and charge it to the fowls at market prices, and all and above what the grain amounted to I considered my own to spend as I saw fit.

I suppose you have all read of the Kansas hen, but I must quote a verse or two in point. It is a new version of Maud Muller and says, in part:

"When Maud is wanting a new spring gown, she doesn't hustle her hay to town; but fills her basket with fresh hen fruit, then goes to town and buys her suit. And when Maud's beau makes a Sunday call, she doesn't feed him on hay at all, but whisks up eggs in a custard pie and fills him full of a chicken fry. O, corn may be king, but it's plainly seen, that the Kansas hen is the Kansas queen."

And Maud wouldn't need a very large basket at the way eggs sell about Christmas time, either. Now, having proved how very profitable the common barnyard fowls are, let us consider the best way to care for them, in order to get the most we can out of them. In the first place, what we want is a type of fowl suited to your needs. If you are raising market poultry, you will want a heavy, meaty sort of chicken; one which will dress out a plump carcass at any age. There are many breeds which answer these requirements, and among them you may make a selection which suits your purpose. It doesn't make any difference what the color of its feathers is, or what style of comb it has, so that it makes the sort of carcass your market demands. Some markets require a fowl that will dress from three to five pounds, and others call for larger birds. Some consumers figure that there are just so many pieces to a chicken anyway and the small birds go just as far as the large ones, and so they do if one's appetite is delicate or one is bashful about asking for a second piece.

Some prefer yellow legged fowls, while some declare in favor of white skinned fowls, and other epicures want none but black legged ones. Whatever your nearest market prefers will pay you best to produce. Having selected your breed, if you cannot at once buy the sort of birds you want, either buy eggs for hatching from those who have them for sale, or else procure males to cross upon whatever hens you happen to have, and breed up by getting fresh males every year. It won't pay a farmer to inbreed. Always change your males every year. Only fanciers can take time to toe-mark and pedigree their chicks, and breed in line.

If you cannot find males unrelated to your own flocks of the same variety, do not hesitate to cross with males of some other breed having the same general characteristics as your own. If yellow legged and yel-

Wm. C. Parker, 111 Pacific Avenue, Santa Cruz, Cal.

low skinned varieties are called for you have many breeds to choose from —Rocks, Reds, Wyandottes, Cochins, Games and Brahmas.

Of white skinned breeds, there are Langshans, Orpingtons, Houdans, Crevecoeurs, Dorkings and Minorcas. The type of the meat breeds and the type of the laying breeds differ greatly and different hens of the same breed show as much difference in shape as do Jersey cows, and should be selected with equally as great care for the purpose wanted.

Selection.

We wouldn't breed from a beef animal if milk and butter were wanted, and neither should we be careless in selecting the layers from a flock, and I am not divulging any secrets if I tell you how to select the laying type of chicken.

The shape tells the story. The lazy layer is round in all her curves, short in back and keel bone, and narrow between her thighs. She is usually fat enough to kill at any age, and takes life easy, as a rule. She sits on the roost a good bit of the time, dreaming, not doing. We get so mad we throw things at her once in a while, just to waken her up, and she rewards us with a surprised and haughty look, then tries to eat our missile.

The layer, on the other hand, is built along different lines. She looks at you out of both eyes, a point some farmers are very particular about. She is wide between the thighs, and has a longer body, both back and keel bone being lengthened, making her oblong in shape. I once described this hen as "flat ironed shape," and the big guns laughed at me, but I had in mind the toy flat irons of my childhood, which represented a hen sitting, and that shape is the correct one for a good layer. Males should be selected with the same care as the hen is, and one can bring about such a change for the better by breeding to this type exclusively that they will be surprised.

In the Inglewood Poultry colony a pen was selected by Hogan system, which is about the same thing as the Potter system, and ten egg type hens were put in one pen and ten meat type hens in the other. The egg type hens laid 152 eggs during October, while the meat type hens laid just eleven on the same feed, which shows how one can pick out the present layers by system, anyway.

House and Location.

So much for selection; now about housing. A roomy comfortable shelter must be provided for the hens, free from filth and dampness, and large enough to shelter them all day when stormy, and warm but not tight. The open-front house is best for this country, but the three sides closed must be wind and water proof, and the roof never leaky.

We don't need expensive houses for chickens, and often some old shed already on the place can be utilized to good advantage.

If the house you have needs fixing and money is scarce, don't despair, but cast about and see if there is not some material at hand of which you can make use. Those of you who have read Mrs. Wiggs remember how the immortal Billy mended the roof with old tin tomato cans, straightened out, and we might borrow his idea and use the big distillate cans which can almost be had for the asking in many places and it wouldn't take very many

BUY CHICKS NOW! DON'T WAIT!

We can sell you baby chicks right now as low in price as when eggs are much cheaper. We can ship safely anywhere within 48 hours. **WE HATCH** 19 varieties of poultry. Send today for price list; it gives full details how we sell and ship chicks, etc. We have satisfied customers everywhere. We guarantee you a square deal. We originated the baby chick business several years ago in Southern California. Our sales, in 1908, exceeded 230,000 chicks, ducks, turkeys, geese, etc. We hatch all of them in season. Write us today. Call and see us —visitors always welcome. Heavy breeds are our specialty.

When the chicks are hatched don't feed them anything for 24 hours, then feed them the best dry Chick Feed you can get. We say that is

West Coast Chick Feed

Read what others say:

SAMUEL R. KELLAM, former president of the L. A. Co. Poultry Association, says: "West Coast Chick Feed is the best feed for young chicks I have ever used. I have given this feed a thorough test, and have always found that it produced fine, large, healthy chicks."

MRS. A. BASLEY, the celebrated poultry authority, says. "I want some more of your West Coast Chick Feed, for it is excellent. It is purer, cleaner and appears better balanced than other feed I had been using, and to tell the truth, I have been experimenting, feeding both together, and they always eat yours in preference."

Ask your neighbors, for there is more of "West Coast" sold in Southern California than all other kinds put together. If not sold by your dealer send us $3.50 and we will send a 100 lb. sack, freight prepaid within 300 miles.

West Coast Mill

of these to cover quite a coop, and if painted and well lapped at the joints would last for years. If your coops have knot holes and cracks in the sides, your birds will have colds and roup, so guard against drafts as you would against contagion. Stop every crack and cranny on the three closed sides and have the open side open so as to escape prevailing winds; mine face east as we have little east wind in Inglewood.

A house 10x12 will shelter 50 chickens nicely. In building a new house, soak every board with distillate, and little trouble will be had with mites, as it penetrates the wood, and an occasional dose on robsts and nest boxes makes my crops so unhealthy for these vermin that they stay out. It must not come in contact with the nesting material, or the eggs will taste of it and not hatch. Fresh eucalyptus leaves are also said to be good to keep lice out of the nests.

Early Beginning.

They say the way to reform a man is to begin 200 years before he was born. So as we have begun with the breeding stock, we can now pass on to the chicks, which should be healthy and easily raised, if the parent stock has been well cared for. The food a parent gets has much to do with the vitality of the chick and hatchability of the egg, and while saving eggs for hatching, it is well to withhold stimulating mashes.

Stimulants.

It is a nice question whether it ever pays to feed stimulating mashes to breeders, and I have not answered it fully to my own satisfaction. I simply don't use them. A neighbor of ours used to run a milk route very successfully, and his method was to keep his cows so fat that the day they fell off to the unprofitable point of milk production, he could turn them over to the butcher, and replace them with fresh cows at the same price. Perhaps we should do the same with hens we force for heavy egg production. Stuff and stimulate them to the limit for a few short months, and have growing up a fresh lot to take their places. I believe some egg ranches do this.—Mrs. Frank Metcalf.

POULTRY QUERRIES.

Yellow Legs.

Will you please tell me if pure bred Leghorns necessarily have yellow legs? We have a flock of fine looking hens—splendid layers—from trap-nest stock, but some of them have white legs. I contend that they are pure bred even if their markings are not up to the standard from a poultry show point of view.—A Truth-seeker.

According to standard requirements Leghorns should have yellow legs, but as you say, even though their legs are white, it does not indicate that they are not standard bred or high standard stock. Many of the birds of all breeds in this climate after they are a year old and even before that, lose the color of their legs, even though they are rich in color when young. We think the dry climate together with the hot sun has something to do with this, so we would not feel alarmed because some of the legs showed white. We know that they will get lighter each year, as they grow older.—F. H. T.

Porterville is already marketing new potatoes.

HOW TO SET HENS.

This seems to be a simple question, but we venture to say that one-half of the failures in hatching and raising chickens with hens is due to the fact that we did not know how.

In the first place, one cannot set hens in the hen house where other hens have access to the nest. If we do, those that want to lay will crowd into the nest and either break the eggs or keep the other hen from returning until the eggs have been chilled. A separate room for setting hens must be provided. A place where they may quietly sit and not be disturbed by others. Any outhouse room in the barn or lot will serve the purpose. The writer has often had as many as twenty hens setting at one time in a single loft room of the barn, and not a single one ever failed to hatch a fair per cent of the eggs.

An ordinary soap box makes a good nest for a setting hen. All you need to do is to cut out a small opening in the side so the hen can step into the nest without breaking the eggs. It will also be necessary to provide a temporary top and front, so that when the hen is first taken to the nest she may be kept there for at least one day. These boxes may be arranged around the wall and the food and water can be placed in the center of the room. Arrange a few nests in advance, and after the hen has begun to set remove her after dark to the room. Carry her gently with head tucked under your arm, set your lantern in front of the nest and let her slip gently on the nest eggs which have already been placed there. Cover the top and front of box and do not disturb the hen for one day. Place a pan of water, box of grit and some corn in front of the nest, and on the second day remove the front and give the hen a chance to come out and eat and drink. If after an hour or two she does not come out lift her off the nest and set her down by the food, with head toward the nest. After she has eaten and drunk she will, if she really wants to set, return to the nest. If she refuses to return, there is no use wasting time with her. After she has settled on the nest, remove the nest eggs and place the other eggs under her. She will come off each day and get her food and dust herself and in no way disturb the other hens in the room. After the second day dust her with insect powder and repeat again on the fifteenth day.

The same covering for top and bottom may be used for other boxes as other hens are set. In this way almost any number of hens may be set in the same room and they will give but little trouble.—Pacific Homestead.

MARKETING EGGS.

The Poultry Breeders of Southern California met in Assembly Hall, Chamber of Commerce, Los Angeles, on Thursday evening, February 25th, for the purpose of organizing an association separate and distinct from the Breeders' Association, for the marketing of their products, especially eggs.

The commission men and hotels are not giving the Southern California local producers the support of their trade, but seem to prefer the cold storage and Eastern eggs to the detriment of the business here. The as-

sociation will embrace all the territory surrounding Los Angeles and hope to control the output of their egg farm in Southern California. Fullerton, Santa Ana, Burbank, Inglewood, Gardena, Pasadena, Monrovia, Anaheim, Glendale, Tropico and other towns were represented and committees appointed to draft by-laws. Another committee was appointed to get a site for a jobbing house here in Los Angeles and these committees will report their progress on March 11th, at which time decisive steps will be taken towards the transaction of business.

It is reported that the city of Los Angeles pays about a million dollars each year for California eggs and about the same for Kansas or Middle West eggs. The dealers have used the storage eggs to hammer down prices on locals, and the producers have stood the treatment as long as they propose to. Juggling with the market has been indulged in until storage have been sold at a higher price than the locals.

Chas. H. Kline of Burbank, is made chairman of the new organization committee and the committee will report at a meeting to be held at Chamber of Commerce hall on Thursday evening, March 11.

BROODERS AND CHICKS.

While a greater number of chicks can be handled to advantage in brooders with less trouble than when mothered by hens, still in some ways more care and attention are necessary.

In the first place, the brooder being inanimate, the chicks have to learn to take refuge in it when the weather grows cold suddenly or a storm occurs, and therefore the attendant has to see that the chicks reach the protection of the hover, for a time at least, and until they learn the way and are able to go to it themselves. Even when such is the case, if a heavy storm comes up suddenly sometimes the chicks become confused and do not enter the brooder, but huddle together, and unless rescued many are either drowned or die from the after effects of exposure.

The brooder also can give no warning when danger threatens, and so the chicks become too fearless for their own good, and unless guarded, will readily fall victims to their natural enemies. For this reason all runs connected with outdoor brooders should be roofed with fine mesh wire and care exercised when the chicks are allowed at times outside these runs.

In the rapid changes of temperature in spring the outdoor brooder has to be watched closely to see that these changes do not affect the temperature of the hover. More harm is undoubtedly done to young chicks from the variation of the temperature inside the brooder than from any other cause.

On the other hand, there is no danger of a hen stepping on her chicks, no danger of a hen killing other chicks of a different brood, if they should come within reach and no danger of hens fighting until one or the other drops exhausted, as many will do with broods of chicks if they get such an opportunity. There is also little trouble from lice, and last but not least, a greater number of chicks can be cared for at one time without that special attention necessary when the chicks are divided into broods with hens.

From the above facts it can be seen that the use of brooders or hens in the raising of chicks each has its advantages and disadvantages, and so the poultry keeper in making a choice should take into account which would in his case answer the best. As, for instance, if he is going to raise large numbers of chicks brooders would probably be the best. If, however, he is raising valuable and fancy stock in a small way, hens will accomplish this to more advantage than brooders.

Outside of this purpose the poultry keeper who does the best work with either brooders or hens should choose the method with which he has had the most success.—American Poultry Advocate.

INCUBATOR HINTS.

Avoid drafts.

Cool the eggs daily.

Don't use poor kerosene.

Keep your hands clean when handling the eggs. It means good hatches.

Keep water on top of the front if possible.

Make a hole in the screw cork of the font.

This lets off the accumulation of gas in the body of the lamp and prevents firing.

Never turn the lamp full height when first lit; the flame "creeps" and grows after lighting.

When there is a big percentage of infertiles the hatch from the balance of the eggs is usually poor.

The time to remedy the trouble is immediately infertiles are discovered. Look to the breeders.

One of the best ways to turn eggs is to remove one row and slightly tilt the tray, letting the other roll gently over. Then replace the removed eggs in the spare space.—The Australian "Hen."

BE CAREFUL, NOT CARELESS.

We can easily lose an entire year's work in the poultry yard by being careless a single day. This may seem strange, but literally it is true—a single neglect, but little in fact, may upset the work we have planned on the past year.

We frequently allow the droppings to remain on the boards for two or three days, or we fail to keep the drinking fountains clean. Often the slightest neglect will cause disorders which upset a whole year's work.

We do not need to pet the fowls, but we do need to make them our friends and prove to them by our acts that we mean what we say. That we mean to give them good food, clean water, grit, and a good clean house to roost in. When we have done this, our full duty has been fulfilled, and if our fowls are good the results will be satisfactory.

2000 LAYING HENS
East San Gabriel Egg Ranch
S. C. White Leghorns and Barred Plymouth Rocks
Eggs for hatching. We fill orders promptly from our selected matings of great egg-producing birds, at $5 per 100, $45 per 1000. At both Los Angeles Shows, 1909, our Leghorns won on firsts, silver cup and special prizes, and more ribbons than all competitors combined. Eggs from prize winning pens $2 per 13.

1st Prize Hen San Jose and Petaluma, 08. **Frank E. Baldwin** The White Leghorn Specialist ***46 Washington Avenue, San Jose, Cal.***

February 6, 1909.

Dear Sirs:—
I have used your Poultry Tonic for a long time and think there is none so good. But you have one remedy, POLLY OIL, I do not feel you know its worth. I had one little sample bottle given me a few weeks ago. I used it on two cases of swell head and it stopped the swelling right away. I had one pullet on which the lump had stayed for over two months, her bill having grown crooked, but as she was a pet I could not have her killed, but could not drive the lump away until I got the sample of Polly Oil. It then commenced to go away, and in a few days is was nearly gone, I have cured every one since that showed any signs of such trouble. I have used all I have and do not want to be without it.
Very respectfully,
FANNIE L. E. WEBBER, Pasadena, Cal.

If not sold by your dealer send the price, 50 cents, and we will send you a bottle, prepaid. WEST COAST MILL, Los Angeles, Cal.

Single Comb White Leghorns
The first essential to success in the poultry business is that the foundation stock or eggs be purchased from a reliable breeder, one who has made a success of the poultry business from the fact that his stock has proven to be the Business Hen. Such stock or eggs we now offer you and stand back of our sales. Prices for stock on application. Correspondence solicited.
Eggs—$1.50 per 15, $7.00 per 100 and $60.00 per 1000.
STUHR-WILLIAMSON POULTRY CO.
378 Bandini Ave. Home Phone 1490 **RIVERSIDE, CAL.**

Starbuck & Son's Heavy Laying Barred Plymouth Rocks
We now unhesitatingly make the proud boast of the best laying strain on the coast, if not in the world. We will publish prices later.
Do you want to hear about our beautiful prize-winning Buff Orpingtons and Silver Wyandottes. We have something to crow about.

General Agriculture

PLANT BREEDING ON THE FARM.

Much greater and more rapid progress in the improvement of farm crops would be possible if in general more careful attention were given on the farm to the methods of seed selection and plant breeding. If, for instance, as much time, thought, and effort were devoted to the matter of crop improvement as are given to the bettering of cultural methods and practices the general results would soon force themselves into prominence and a much greater benefit from the work and discoveries of our specialists and scientists would be realized.

Certain lines of wheat improvement, particularly those to increase the yield and to better adapt the crop to local conditions, are considered simple enough for any intelligent grower, but methods of seed improvement are seldom found in use. About the only method ordinarily employed is the separation of the plump and heavy seed from the poor and light seed by means of screens and air blasts. Some systematic method of breeding simple enough to be satisfactory for general use should be generally adopted.

Unlike the corn plant, wheat is normally self-fertilized, almost no crossing occurring naturally, and for this reason the individuals or plants grown need not be isolated as in corn breeding. Doctor Webber of Cornell considers it possible that without resorting to the generally complex methods of hybridization and selection practical farmers may produce valuable varieties and also improve the yield of their own crop. The methods by which this may be accomplished are: (1) The selection of chance variations or sports and the propagation from them of improved varieties; (2) the systematic selection of the best-yielding plants from a well-known race to secure better-yielding strains; and (3) the selection of large heads for seed.

While sports or mutations of wheat plants are very rare, the farmers watching for such superior plants and testing them are even less numerous, and therefore most of these valuable hints of nature are lost. Every farmer should study different varieties of individual plants until he can recognize exceptional plants as to size of head, yield, quality and size of grain, number of stools, strength of straw, and other desirable qualities. The search for promising plants should be begun as soon as the crop shows mature size of heads, and when such plants are located they should be marked so that the seed may be secured when ripe. This work need not be limited to the selection of actual sports or mutations, but should include generally superior plants, and by selecting as many of these as circumstances will permit the probability of securing an individual of exceptional value is greatly increased. The seed from each selected plant should be kept separate and weighed, if the facilities are at hand, in order that comparisons may be made later on. Each one of these plants, which are the first generation selections, should be given a number and briefly described.

It is recommended that the seed of each plant be planted separately in a short row on a clean and well-tilled piece of ground. These rows may be placed one foot apart and about every twentieth row should be planted with some standard variety for comparison. At the beginning of the ripening period the season of maturing of the different rows must be observed to determine their relative earliness or lateness, and when fully ripe the rows should be compared with each other and with the rows of standard varieties. Only those rows apparently ranking high in yield, free from or least affected by disease, such as rust or smut, showing no tendency to lodging or shattering, and those indicating the greatest hardiness should be selected for further propagation. After the superior rows have been chosen each row must be examined for uniformity of type, and all plants not conforming to the general type pulled out and discarded. The grain or seed of each row is harvested and kept separately and given the number of the individual plant first selected. The record of yield, earliness, hardiness, etc., of each number must be carefully preserved.

The seed secured from these first generation selections is used for the propagation of the second generation according to the following plan:

Plant a drill row 17 feet long, using a definite rate of seeding; one-half ounce of seed per row would be at the rate of about 1½ bushels of seed per acre and should be thick enough. These 17-foot rows should be planted 1 foot apart, so that one row represents one-sixteenth of a square rod, or one two-thousand-five-hundred-and-sixtieth of an acre. Plant as many 17-foot rows from each kind as the amount of seed obtained will plant, but if more than one row is planted place them in different parts of the field, in order to obtain a better judgment of the variation due to soil. In planting the 17-foot rows at least every twentieth row should again be planted with a standard variety for comparison.

When the grain is ripe all inferior rows are again discarded, the best rows harvested separately, the grain from each row weighed for comparison with other rows as well as with the standard varieties, and the results recorded.

The third generation is grown in 17-foot rows from the seed of all of

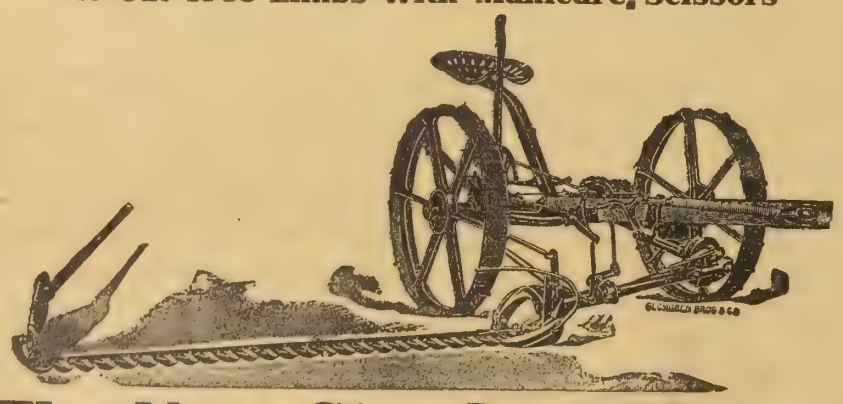
PLANTING TREES ON ARBOR DAY IN SAN JOAQUIN COUNTY.

Did You Ever Stop to Think

That the Lightest Looking Mower Is Very Apt to Cut Heaviest;

ALSO

That Only a Very Foolish Person Will Try to Cut Tree Limbs with Manicure Scissors



The New Standard Mower

All power in a Mower originates from the grip of the wheels on the ground,—the firmer the grip the greater the cutting power.

The 5-foot New Standard Mower weighs 825 pounds. The entire weight of the cutter bar (while cutting) is transferred through the suspension spring to the main wheels. The bar is neither pulled nor pushed,—it is carried—an exclusive Standard feature.

The power thus secured is transferred to the gearing through the mechanically perfect wheels, found only on the New Standard Mower. The gearing develops high speed without undue strain and passes the power to the knife. The knife works in our famous curved Cutter Bar,—the only frictionless knife channel made.

These are a few reasons why the New Standard Mower is the most powerful cutting mower made.

A folder giving full detailed description of the New Standard Mower and our other Haying Tools will be mailed free on application.

Newell Mathews Co.

200 North Los Angeles Street

Los Angeles, California

the second generation rows selected, and the results of this year should point out the best-yielding strains. It is advised that of a few of the very best and highest-yielding strains somewhat larger plats be grown this year to increase the seed for more extensive planting in the fourth generation. A few of the best-yielding strains should be saved from this year's crop for more extensive trials in the fifth year.

For the fourth generation 17-foot test rows are planted with the strains retained from the third generation and these are compared with some standard variety. If possible, several test rows of the standard varieties should be grown in different parts of the test plat. At maturity the grain of each test row is harvested and weighed separately, as heretofore, and the yield records carefully made and preserved. By comparing the yields of the test rows and increase-plats of each strain for the three years with each other and with the yields of the standard varieties the highest-yielding strains to be retained for extensive trial may readily be determined. All strains inferior to any other grown and to the standard varieties should be discarded. At this point of the work it is suggested that but two or three strains, or only one, if it is markedly superior, be retained for planting as large a field as possible the following season. If the results show that a superior variety of a high-yielding capacity has been secured the seed should be distributed as extensively as the quantity justifies, and if extensive tests prove it to be a superior variety it should be given a distinctive name.

The method just presented is based upon selecting entire plants and getting the total product of different plants in beginning the selection. In some cases large fine heads from apparently good plants are selected and the product of each head or ear planted in a row by itself, the same as is described for planting individual plants, except that since there will not be seed enough for the 17-foot row the rows are made shorter in accordance with the amount of seed in the heads selected. Ordinarily these will furnish enough for one or two 17-foot rows the next season and the further tests are carried out exactly as already described.

The selection of well-known races to secure high-yielding strains should be carried out in different years in exactly the same way as above outlined. A standard variety, well adapted to local conditions, may be improved by selecting and testing the highest-yielding plants. The tests of these plants through the several years are carried out exactly as described for the selection of chance variations and sports.

The simplest application of the method of selecting large heads consists in examining the field of a good standard variety and gathering a quantity of the largest heads, at least enough to make a bushel or more of seed. The following year this seed is grown in an increase-plat and when the grain is ripe it is again gone over and enough large heads gathered for a similar-size plat the third year. The remainder of the crop of this increase-plat is used to plant the general crop of the third year. This method continued year after year will result in good seed for planting.

That the grade of seed wheat generally used is not up to the standard was ascertained in an investigation by G. W. Shaw, of the California Station, who secured a large number of samples of seed wheat over a wide area in the Sacramento and San Joaquin valleys of California, to determine the general character of the seed used by the farmers of the State. In general the samples showed that the quality of seed used by most farmers is lacking in purity, perfection of development, weight per bushel, freedom from weeds, and freedom from bunt. It is stated that practically all investigators have found the use of large plump seed and of a high weight per bushel the most profitable. No permanent benefit is believed to be secured from the frequent exchange of seed unless a better type of wheat or a more vigorous strain of the same type is obtained by the exchange. The use of seed from heavy-yielding plants, a plump and heavy grain, a clean wheat, and a pure variety are considered by him the most important points in seed selection.

At first thought it would seem that if "like produces like," the large or heavy seeds should produce the best crop. However, we must recognize the individual plant as the unit for selection, rather than the individual seed. If a single plant of wheat be taken and the kernels thrashed out it will be found that all sizes of kernels are produced by the plant, some large and some small.

As every wheat plant contains both heavy and light seed, the fanning mill gives almost the same kind of wheat so far as inheritance is concerned in the light wheat as in the heavy. It must be remembered that reference is made here to the permanent results which may be expected from the use of the fanning mill and that its use or the use of screens for removing abnoxious weed seed is in no way discouraged, and where a large proportion of the seed grain is shrunken, immature, or damaged this method of seed selection will without doubt increase the following crop by the removal of the poor seed.

AN APRICOT ORCHARD IN COLUSA COUNTY.

MORTAR.

To make mortar take one part lime to four parts sand. Mortar for laying bricks should consist of one part lime to two and one-half to three parts sand, depending on the quality of the lime. All mortar for plastering should be allowed at least one week for the thorough slaking of the lime and a complete permeation of its caustic properties.

SERIOUS INTERRUPTIONS.

The truly lazy man is not a common figure in this country, and when he does appear he is not treated with proper respect. Ideal laziness is an art as difficult as playing on the violin. A writer in the Washington Star tells of one member of the Sons of Rest who deserves recognition.

"I s'pose John is still taking life easy?" said the woman in the spring wagon.

"Yes," answered the woman who was carrying an armful of wood. "John has only two regrets in life. One is that he has to wake up to eat, and the other is that he has to quit eating to sleep."—Youth's Companion.

Bees and Their Care

HUMANIZING INFLUENCE OF BEE KEEPING.

SOME time ago a Vienna Bee Journal published the story of a German bee-keeper's attempt at straightening out his apicultural finances at the end of the year. Entering his bills and things in one column and the income from honey and wax in another he found in comparing the totals that he had run behind about 200 mark. Involuntarily, a deep sigh escaped him. His wife who sat near looked up with a mingled expression of satisfaction and pity, and with a note of sarcasm in her voice inquired what the trouble was, now. He handed her the book. "Just what I expected" she railed at him, "another bagful of money gone, the same as last year, and the year before that, and nothing to show for it. I begged you to sell out last year, but, of course, I don't count. I don't suppose you are ready now?" Yes, he would sell, if she really wanted him to, "but listen a moment."

Amateur Beekeepers Place in Thuringian Forest, Germany.

"Outside of your company, when you are not too disagreeable, my work with the bees has been the delight of my life. I have, of course, my work and duty among the people, and much of that, too, is delightful. But at times shadows creep in, and darkness imprisons the mind; disappointments and worries, of which you mostly know nothing, gnaw at the vital cord like a loathsome worm, and I feel sullen and bitter—a friend of nobody. And then I go to my bees and watch them at their work.

"At first I scarcely see anything. But bye and bye the going and coming of them draws attention. Going—as they come out at the entrance, single and in broken rows, take wing with the joyous spring that speaks of rich pastures and blooming meadows somewhere, and disappear in heaven's blue. Coming—loaded with the pure and precious sweetness of a thousand flower hearts, too heavy and tired at first to go in, but alighting near enough their treasured home to walk in after catching a breath. I watch that, and in watching I forget the things that troubled me. And sometimes I look inside. And as I observe the order and precision and cleanliness there, the unstinted self sacrifice with which the mother bee follows her life work, the tender solicitude of the young workers feeding and caring for the thousands of helpless babes; the mathematical precise cellwork of another portion of the inmates, the intelligent disposition made of the honey and stores—how not a single individual of the tens of thousands of the inhabitants of that marvelous state works or cares for self, but only and always for the community, how freely they offer up their short little life in defence of home—when I watch all that, I say, and try to comprehend the meaning of it all, a feeling of awe steals over my mind, and I seem to be standing with Moses at the burning bush of the Mount of God, and to hear the voice out of the bush: "Take off thy shoes from off thy feet, for the place whereon thou standest is holy ground;" And then I come away humble, self lost, grown a little nearer, I trust, to a likeness of the white-robed ones above.

"And then there is another thing. Instead of spending my leisure time with my chums playing cards, or other games, becoming more or less detached from you and home, I staid right here. We have become one anothers mate and comrade, our life has become knitted closer, our children have had better care and guardianship—if that, now, is anything to you the bees should have some credit for it. Yet, if you still think I had better sell them, why, then, off they go as soon as somebody will have them."

There was no word from her. But he observed her eyes gleaming with moisture, and a quiver playing around her lips, and then he, too, was silent.

And so in our beautiful California of the more mature faces one meets coming and going, how few there are that express the peace and sweetness that might be there if self and dollars were more subordinated, and in the doing of one's appointed work one would do it in the spirit of service rendered society. And beekeeping, amateur beekeeping, can invoke that spirit as few other occupations can. The thing is so easy, so inexpensive, so full of reward for work well done, so inviting even to the highest type of mind, with its mysteries and perplexing problems.

There is scarcely a place in city or country where a few colonies may not be kept with profit and pleasure. Of course, the paradise for the honey makers lies spread over the hills and mountains. Soon, in a week or two, now, the vernal stir of another oncoming season of blessedness will call from out the Deep the open eyed children of a thousand ages; the purple blue-bell of the hidden dell; the sky blue phacelia with its fern like foliage hiding under the skirts of the sage brush; the delicately tinged sages massing together their serrated flowor knops; the gorgeous poppies, the bloodred rhododendron, the yellow azalia flowers no bigger than a pin head, and flowers six inches across, of every imaginable variety, and form, and color, all beckoning to the honey bee with their gift of sweetness, all speed and prosper her on her way as if that was their only business.

Later on, in April and May, as the ozone from the sea drifts in and gathers up and so commingles the perfume and spice of miles after miles of flowers and herbs, the soul cleansing, lung healing, flesh soothing essence of them all, he who at such time has his appointed place and work in the midst of a populous apiary in canyon or arroyo, on mesa or hill, and does not, sometimes, feel a softening glow steal over his heart in contemplation over the abundance of the enveloping goodness, or a tear roll down his heated cheek, must belong to a primitive order of mortals, indeed.—Henry E. Horn, Riverside, Cal.

MINUS QUANTITY.

(Continued from Page 274.)

this form nourish plant life. It is altogether probable that these plant foods become available to plant life through the agency of the humus compounds.

Humus as a Soil Sponge.

Humus acts as a sponge in the soil in its water absorbing powers. Like all other kinds of organic matter it holds water very much better than does mineral matter. A soil well supplied with humus may hold nearly twice the water that a medium sand will carry, and one half as much again as a medium sandy loam. When we remember that plants use from 250 to 800 times their dry weight of

SURETY BOND
INSIDE EACH ROLL OF
CONGO ROOFING

With the 3-ply Congo Roofing sold hereafter there will accompany each roll a Guarantee Bond, issued by the National Surety Company, insuring to the purchaser a good roof for *ten years at least*. The bond covers that space of time—but we are very confident that with the ordinary care and attention called for Congo will last much longer.

Congo is so thoroughly durable, reliable and altogether satisfactory that we have no hesitancy in offering our customers this security.

Congo has achieved for itself a reputation as the "never-leak" roof, which it sustains through all the vicissitudes of weathers and climates.

This bond is issued as a proof of our belief in Congo and the National Surety Company stands *back of it* and back of every roll of Congo made. We know its worth and usefulness and want everyone who has a building to roof over to know the satisfaction of a Congo Roof.

To-day is the time to write for a sample and full information regarding this special offer.

water during the growing season and that under the California conditions it is of extreme importance for us to care for all the water which falls it will be seen how vital the question of maintenance of a good humus supply is. Under the present conditions it requires a greater rainfall to produce the same amount of dry matter than it did twenty years ago on account of the lessened humus content of the soil. Not only does the humus absorb a greater quantity of moisture and hold it against drainage losses, and for the use of the plant, but it assists greatly the capillary rise of water, thus promoting growth in dry season, the moisture being more slowly and evenly conveyed to the plant roots. The presence of ample humus supplies in the soil means success: its lack means disaster. The water-holding capacity of the soil may be lowered a quarter by reducing its humus content by one half. The original moisture capacity of the soil and its pristine vigor may be largely restored by re-stocking the soil with humus.

Humus Increases the Warmth of the Soil.

As black clothes are warmer than white ones, so the dark color imparted to the soil through the presence of a liberal quantity of humus will render the soil warmer, consequently the crop is thus made earlier and frequently frost injury warded off, although it is admitted that it might happen that so much humus was in the soil as to actually cool it on account of the slowness with which the water held by it tends to evaporate, so that in case of soils very rich in humus the cooling effect might overbalance the increment of temperature due to the change of color. This latter condition, however, is seldom found in agricultural soils.

Humus Betters the Soil Texture.

By the incorporation of this organic matter in the soil, the porosity of the latter is increased and soil aeration bettered, and the weight of the soil is lessened and thus the increased pore space and lessened weight tend to promote easier tillage. As contradictory as it may seem, sandy soils are made more compact and retentive of moisture, while clay soils are made more mellow and porous by this vital thing, humus. It must always be remembered, however, that this easier tillage leading to a cleaner culture serves rapidly to deplete the soil humus supplies and special pains must be taken to restore that which is constantly used up, owing to tillage.

How May the Need of Humus Be Diagnosed?

First, by one's general knowledge of the past history of the soil; Second, by observing the relative action thereon of farm manures and of commercial fertilizers. By the tendency which the soil has to bake or to dry out rapidly or in the case of lost soils the drift will be vastly improved by the addition of humus.

RICH COUNTRY ABOUT SANTA PAULA. (Courtesy Santa Paula Chronicle)

It would require too much time to enter into a discussion of the effects of current agricultural methods upon the humus content of our soils. The condition of many of them is a standing commentary upon such methods. Suffice it to say that clean culture while conserving moisture tends rapidly to burn out the humus and thus rapidly deplete the soil and with this loss the humus goes, also a serious loss of phosphoric acid, potash and lime.

A grower, if he is wise, will keep some sort of track of the plant food outgoes and so adjust his procedure as to maintain the plant food, or at least to minimize the losses. There is much difference as to the effect of the character of farming upon the soil losses. In grain farming, there has been a very serious loss of nitrogen, phosphoric acid, potash and lime, especially from the top foot, in addition to rendering the top soil extremely refractory in cultivation. It is neither the time nor place to discuss the methods of restoring these grain lands.

The horticulturist is engaged in special farming, one which constantly withdraws plant food from the soil, and he has no recourse to any great extent to farm manures to assist him in the maintenance of the fertility of his soil. He is forced then to a more natural system, on the one hand to maintain the humus supply by the use of green manure crops to be turned under, and by the artificial application of plant food on them through the use of commercial fertilizers. But right here comes a source of danger for the continued use of commercial fertilizers alone tends to aggravate the trouble by the exhaustion of humus. They supply little or none.

The function of fertilizers is to augment crop growth, which means the use of humus. If we are to maintain soil productiveness by the use of commercial fertilizers alone, special measures must be employed to maintain the humus content, else rapid deterioration in this direction occurs. This should not be construed, however, as an argument against the usages of commercial fertilizers, but rather a plea for their proper usage in connection with and not in lieu of humus material. No one can hope to secure maximum returns from commercial fertilizers unless there is a reasonable amount of humus existing in the soil.

A Spendthrift.

This brings us to the question as to how one may maintain and augment the soil humus. This may be accomplished by these procedures, all practicable, standard and long practiced by the best farmers, viz., (a) crop rotation, (b) the use of farm manures, (c) the practice of green manuring. While the first named, crop rotation, is not available in orchard practice, yet on account of the fact that many fruit growers are also interested in other farming operations it is pertinent to say that crop rotation retards where continuous cropping hastens soil deterioration. The one maintains a higher degree of fertility, assists in the regulation of labor, aids in the combat with weeds, and makes for success, the other lowers fertility, reduces yields below the point of profitable farming, is a spendthrift of humus. Rotation should be short and include leguminous crops. The fundamentals for this practice are to select three classes of crops, one which will sell well, one which has fertilizing value, and one tending to free the soil from weeds—money, manuring and cleansing crops.

As to the second method of securing humus, viz., the use of farm manures, I assume that no one is so foolish as to neglect their use when obtainable at a reasonable cost. Rich in organic vegetable matter, already partly decomposed in condition for and containing agents inducing rapid decay, it is ideal and rich humus of the best sort. No one gets its maximum value; many get but half.

The third method, viz., the use of green manure crops, is well recognized in the southern part of the state, but in the north farmers have not as yet realized its importance. It is the method, par excellence, for securing humus. The most favorable crops for use in California are the Canadian Field Pea, the Vetch, or Winter rape. It is seeded in the fall and turned under in the spring. It affords the most natural and the cheapest method of maintaining a good humus supply.—G. W. Shaw, Berkeley.

WE INTRODUCE

Crimson Winter Rhubarb

Into New York and Philadelphia, and other Eastern Markets. Let us tell you more about our methods of introducing California Products under a Guaranteed Label.

We understand eastern conditions, eastern markets, eastern people, their likes and dislikes.

How to put up shipments in an attractive manner. We do not dump our goods on the Eastern Commission Houses and take a chance on getting a price. No! We go right out and create a demand among the high grade dealers under a special brand, and That Brand is a Guarantee that the goods are special first class. Our men are working among the Eastern Trade all the time.

EVERY GROWER AND SHIPPER

No matter what their present arrangement may be, should write us for information, for by our plan you receive the best prices paid in the Eastern Markets.

Queries and Replies

Questions to be answered in this department should be received at this office one week before reply is expected. Write plainly on one side of the paper and sign full name and address. Unsigned communications receive no attention.

Catalpas From Seeds.

Please tell me how to start catalpa trees from the seed, also will palms be injured much by frost and cold weather in upland valleys Subscriber, Newberry Park.

Catalpas are started from seed sown in flats very much as are eucalyptus. The prepared loam soil is spread in the flat and levelled. The seed is sown lightly over the top and a light surface of sand or very fine mulch of leaf mold. They should not be allowed to suffer from want of moisture and later may be reset in nursery row.

Many of our palms are purely tropical and will stand no frost whatever and the only culture in this country is indoors or in glass houses. As to whether the Washingtonia or the Canariensis, the so called date palm, or other ornamental palms will stand the cold can only be known by having more definite idea of the temperature. Doubtless Ventura county could, grow these palms to perfection in practically every section.

Fodder.

Will you kindly advise me through your Queries and Replies column, the best fodder food that grows without irrigation on adobe soil? Would you advise cow peas or cow peas and oats sown, or sorghum?—W. G. S., Los Angeles.

We would refer the inquirer to observation of H. A. S., and Mrs. Sherman's notes on same. Regarding cow peas, if they are to grow during the cold season as we assume they must without irrigation, they would not answer. It must be borne in mind that the cow peas are beans and will not grow during the colder weather. Canadian field peas would be better, or the ordinary Blue Prussian. Sorghum is excellent and we would refer the inquirer to many articles which Mrs. Sherman has written on the advantage of sorghum.

Green Forage.

I have made a discovery that may be a help to your Cultivator column. In August I irrigated some ground and in September sowed it with White Australian wheat. Two acres have kept a cow and a calf and yet half of the wheat is three feet high and has leaves an inch wide. Such sowing in orchard would furnish wonderfully good pasture for hogs, calves and colts.—H. A. S., Kerman.

Yes, the wheat sown early that way will keep much stock. The manure we haul out on the land in the summer starts to grow at the first rain and gives us feed by January a foot high. We pasture it off with the stock in the vineyards and orchards. The malaga grapes that are shipped early, as well as the olive orchard has carried much of our stock. If I was sowing this crop in a orchard for feed I would sow at the last cultivation of the summer time the common green peas and let them come up with the first rains. These are more valuable for nitrogen production in the orchard. The tops grazed off and the roots turned under helps the soil considerably.

The black eye pea is a bean and last summer we had them cover the ground three feet deep over most of the young orange orchard. They were chopped with the discs and plowed under in November and by January 1, had rotted completely.

The tops we did not harvest in the orange orchard as the land is heavy and we were after the humus as well as the nitrogen. This orchard has not been boggy all winter for we have hauled the stable manure there daily when we could not get it elsewhere on the wet soil. There is more money in dressing the pigs and feeding them to the men when they weigh a hundred pounds than in turning them off to the market.—M. E. S.

No Weedy Ditches.

I am making up a lot of cement tile—12 and 18-inch—to carry water over difficult places. I intend some day to eliminate the open ditch, though I have rigged up a rotary harrow with sweeps or cups that keep ditches up sharp and clean. It is a great deal of work, however, but weedy ditches are an abomination.—H. A. S., Kerman.

We have tried many plans on the ditches and find the cheapest is the revolving harrow, then a good chinamen to burn them and then plow them with two horses and follow right along with a V. This makes it straight work. I do not like anything planted on the ditch banks for that reason. The cement ditch would do away with the cleaning and in places where the seepage is too great they are a good thing, yet in dry years the seepage of the ditches when they are kept full of water prevents the need of surface irrigation. The ditches on the ranch seep 250 feet. I have tested this by digging wells beginning at a hundred feet from a dry ditch and going again fifty feet further, then filling the ditch with water. In three weeks the water would appear and in six the well would fill up to within a foot of the top of the ground. I therefore simply have ditches a thousand or eight hundred feet apart and fill them full to the top to do the irrigation, beginning in January they have the land filled with water by March 1st, and the water is let out and the plowing begins. Some of the land has to have the ditches a little closer, but usually the distance given will put in enough water for the season. The water table then drops steadily as the plants grow until it is down to the right distance by June 1st.—M. E. S.

Bitter Cow's Milk.

Will you please tell me the cause of a cow's milk becoming bitter after twenty-four hours standing? She has not been fresh for three years. Does that have anything to do with it? It cannot be caused from eating weeds as she has good alfalfa pasture.—Subscriber., Corcoran

This is not caused from the feeding or from the fact that the cow is farrow. It is simply caused by a bacteria that grows during the cold weather and the way to overcome it is by thoroughly washing all utensils, following with abundance of boiling water and finally water in which lime is mixed. Be careful in stable, also, of allowing any dust or possibility of bacteria coming in contact with the

Now is the Time
To Plant
Eucalyptus Trees

I have about 200,000 seedlings left, price $7.50 per 1000 f. o. b. Corona. Varieties, Rostrata or Red Gum, Corynocalyx or Sugar Gum, Rudis or Desert Gum, Tereticornis or Grey Gum.

Robt M. Wollitz, Corona, Cal.

milk. Observe care and we think you will have no further trouble.

Canaries Eating Eggs.

I have several canary birds that eat their eggs as soon as laid. The habit seems to be contagious. Can you tell me any means of prevention? Subscriber, Capay.

If any subscribers have had experience along this line and have corrected the habit, will they please give us the information desired? In a general way we will say the habit is started from a lack of properly balanced food, especially possessing a lack of lime, but once started it is a very troublesome habit and very hard to break. With poultry, we have before now wrung the necks of many hens who have started the habit, in order to get them away from the rest of the flock which seemed to learn from them. If you have birds which have not formed the habit we would surely separate them, then try to correct the feed and the habit in the others.

Flat Head Borers.

Is there any way to prevent borers from getting into young apple trees I have planted, and what time of the year do they start work? Would whitewashing them and putting wood ashes around the bottom do any good? —Subscriber, Madera.

The answer for this is given in the reply to a similar query. The first factor is to prevent any sunburn of the bark of the young trees. This may be done by the whitewash given above or by the fibre or paper tree protectors sold in the market, or in addition to the above given whitewash the following is good: Fresh lime 25 pounds, whale oil soap six pounds, water to slack and make of proper consistency. The adult beetle will appear a little later than this, probably in May or as early as April and lay its eggs on the trunks and branches of trees. They prefer the sunburned and partly dead wood so that thrifty trees are less liable to their attack and the whitewash is an additional preventive.

Hollow Tail.

Tell me what to do for a cow with hollow tail. I have a cow just come in with her second calf in good condition, but when she calved she did not do well, ate but little, and did not give much milk for several days. I find she has a hollow tail, that is the end of her tail has no bone in it for about four inches. She is now doing all right. Should I do anything for her.—Subscriber.

Hollow horn and hollow tail are diseases of the human imagination. A little before a calf is born the cow drops down a little at the butt of the tail and also as a cow grows older the tail will show this condition. The usual remedy for these troubles is to stiffen the cow up with plenty of feed and then the trouble is gone. Hollow tail and hollow horn come from hollow stomach more than anything else. —M. E. S.

Fillarie For Green Manure.

I have here in my young orange orchard the soil covered with luxuriant growth of fillarie. Sometimes as much as two feet high. Has it any value to plow under? Would it be advisable to kill it out and sow peas or clover A part of the orchard is on a hill side and it certainly keeps the soil from washing during the winter rains. Are peanuts sowed with the shells on or off?—H. G., Lemon Cove, Tulare County.

The fillarie is surely worth plowing under and will have a beneficial effect upon the soil and as you say has certainly saved heavy washing this winter. It is not a legume and has not the power of grasping from the air the nitrogen which the legumes have, hence the humus from it has not that value which is given by the leguminous plants. Ordinarily we would prefer the legume but as you say the growth is so heavy that the saving of the soil is a great consideration we would not kill it out, but believe it might be advisable to put in with it either the peas or vetch and allow them to grow up together.

Peanuts may be planted with or without the shell as preferred. Usually they are not shelled.

Identification of Vine.

A subscriber sends leaf and asks if same is from the Lippia Repens? The letter and the leaf were sent to the botanist, Dr. A. Davidson, and the letter has unfortunately been lost. If the subscriber will write again with stamped envelope we will be glad to mail slip of Lippia, which will help subscriber to determine what the Lippia leaf is like. Judging from the leaf sent, Dr. Davidson says: "This is a Speedwell, probably Vernoica Buxbaumii, a garden escape in some districts." It is a native of southern Europe that has been naturalized in North America.

Poisoned Wheat.

Will you kindly inform me through your paper of the following? How can I prepare poisoned wheat with cyanide of potassium? How much crude carbolic acid to one gallon of whitewash for using on trees to prevent attacks of flathead borers?—W., Sanger.

The formula for making poisoned wheat from cyanide we have not at hand, but give here one which may be equally as good, or if you prefer the cyanide it may be made along the same general line except you will not need vinegar to dissolve the poison as in the case of stfychnine. The strychnine formula is: One ounce strychnine crystals dissolved in one-half pint hot vinegar, add two pints hot water, pour this over twelve pounds wheat stirring several times until the water is all absorbed and spread on paper, of course where it is not accessible to children or to stock. Allow wheat to dry and when dry pour over it a syrup made of one pint of water and three pounds sugar, which have been boiled until it candies when dropped in water. Stir the sweetened mass until all is well mixed. This may be done in an earthen vessel as it is easily cleaned and leaves no danger of poisoning. When ready to use it, take four or five drops of anise oil to each pound of the poisoned wheat. The soaking of the wheat in the poisoned water before adding the syrup is preferable to the method of making syrup and poison in one mass. There is danger in such cases of the sugar hardening and flaking off, leaving the wheat without any poison.

We cannot give you information as to amount of carbolic acid but think it should be a very limited amount. Here is, however, an excellent formula from California Fruits: 30 pounds lime, four pounds tallow, five pounds salt with sufficient water to make flow well.

Tuberculosis.

I have a fine jersey cow. She looks well and fat but has a cough and her hair seems to loosen when I curry and brush her. I sometimes think it will all come out and she seems to have a skin disease. The skin gets hard and stiff, then breaks out in sores which seem to be itchy. There are little warts on the udder.—Subscriber, San Gabriel.

I should test this cow with tuberculin before I tried anything else. If she does not react to it, then clean up wherever she has stood with by whitewash with carbolic acid in it. Then treat the skin just as you have been doing. The trouble may be that she reinfects the skin from old disease germs around the stable. If this is the case it should disappear if you destroy it on all the surroundings as well as on the animal herself. You might try this before you have her tested if you desire to do so.—M. E. S.

One winter's day a very bow-legged tramp called at a home in Ontario and stood to warm himself by the kitchen stove. A little boy in the home surveyed him carefully for some minutes, then finally approaching him, he said, "Say, mister, you better stand back; you're warping."

All Soils Alike to Wood Pipe

SINGLE COMB RHODE ISLAND REDS —eggs for hatching $2.00 per 15. F. D. CRAWFORD, South Dos Palos, Cal.

CALIFORNIA'S OIL PRODUCTION.

The value of California's oil production in 1907 exceeded that of any other mineral product, and the State was second in rank among the oil-producing States. From the best information available at the present time it is believed that the production of crude petroleum in California in 1908 will aggregate between 44,000,000 and 46,000,000 barrels, exceeding that of 1907 by about 12 per cent. Nearly every district shared in this increase. This condition was brought about by the increasing demand and consequent higher prices for oil which stimulated drilling, particularly in the Coalinga and Kern county districts. Much development work was carried on in Coalinga and the field was extended; in Kern county many new wells were brought in and many old wells which had not been pumped for several years were cleaned out and operated.

The completion of the pipe line in 1907 and the building of the railroad to Midway, together with the construction of the new rifled pipe line of the Associated Oil Company from Kern River to tide water, did very much to encourage drilling and increase production. The past year was one of greater activity in the Santa Maria field than ever before, but the output of this field, which in 1907 gave promise of being enormous in 1908, was considerably lowered by the presence of water. Some of the wells have an extraordinary yield and the field leads all others in the state in rate of production per well. More crude oil was shipped from the fields of Southern California in 1908 than ever before. The greater part of the oil exported from California comes from the Santa Maria field, its situation giving it command of the coast trade from Alaska to Chili and of foreign trade with Japan and Hawaii.

No new oil fields of importance were discovered in California in 1908, although petroleum was discovered in several places, one being near Mono Lake, in Mono county.

BERRY PLANTS.

STRAWBERRY PLANTS—FINE ONES, strong, thrifty, restricted Kellogg method, best varieties, Marshall, Jessie, Climax, and Everbearing. $3.00 per 1,000, $12.50 per 5,000. To close the season all plants are one-half prices quoted above while they last. Address J. R. POWELL, Ripon, Cal.

TWO SCHOOLS.

I put my heart to school,
In the world where men grow wise.
"Go out," I said, "and learn the rule;
Come back when you win the prize."

My heart came back again,
"And where is the prize?" I cried.
"The rule was false, and the prize was pain,
And the teacher's name was Pride."

I put my heart to school,
In the woods where wild birds sing,
In the fields where flowers spring,
Where brooks run cool and clear,
And the blue of heaven bends near.
"Go out," I said; "you are only a fool,
But perhaps they can teach you here."

"And why do you stay so long,
My heart, and where do you roam?"
The answer came with a laugh and a song,
"I find this school is home."
—Henry van Dyke in the Atlantic.

THE FIRST QUARREL.

It is said they all go through it some time or other, generally in the early part of the married state. Here is the way it was:

They had been married two weeks and were settled in a Harlem flat. He sat in the Morris chair, smoking with apparent contentment, but there were signs that he was a bit restless. She idly picked up the evening paper and glanced over it, but no divorce suits were chronicled at any length and there were no new affinity cases—practically nothing but whole pages of politics, so she tossed the paper away. There were a few desultory observations from each other, but, strange to say, it seemed a trifle diffcult to keep a conversation going. Of course there was the eternally fruitful topic of themselves and what each meant to the other, but this subject had been so thoroughly discussed during their honeymoon that neither felt exactly like taking it up again now. They were trying now to ignore their newness to each other and wanted to seem settled and married-like. So there was a hint of uncertainty, a vague uneasiness in the air. Hubby glanced at his bride as if he felt that in his capacity as head of the household and her lord and master it was up to him to do or say something or other, but he didn't know what.

He glanced at her again. Their eyes met, and instantly each looked off somewhere in an attempt not to seem self-conscious. Finally he spoke:

"Wouldn't you like to go to a show this evening?"

"Why, I don't know; do you want to go?" inquired the bride sweetly.

"Why, no, not specially; but I thought maybe you'd like to go."

"Why, yes, I'd like to go if you think you'd care to."

"Well, I don't particularly wish to; but I thought if you felt as if you wanted to see a show, why, we'd go."

"But I don't want to drag you out with you looking so comfy and fixed!" protested the bride affectionately.

"How absurd-" said hubby fondly. "That doesn't matter if you think you would like to go out."

"But I don't want to go if you're coming along just because you think you're pleasing me."

"Nonsense! Why, I want to go if you want to go."

"Yes, that's just it! But I don't want to go unless you do."

"But then it will give me no particular pleasure to go to a show unless I know you are enjoying it."

"Why, of course I will enjoy it if you're along."

"All right, then," said he promptly. "Come on and we'll go."

"But just now," said she anxiously, "you said you didn't particularly care to; I am sure I shouldn't want to go unless I felt that you were getting as much fun out of it as I."

"Fiddlesticks!" He said it a trifle impatiently. "Now listen to me and answer yes or no—do you or do you not want to go to a show?"

"Why, you know, Harry, I'd just love to, but—"

"All right, then, we'll go!" exclaimed he a bit shortly, springing to his feet.

"But I'd be perfectly miserable all the time," said the bride, "thinking that you'd come just to please me, and that we might have had a cozy little evening at home if—"

"All right, then, we won't go," manfully repressing an impulse to anger and replying resignedly as he sat down again.

He picked up the paper and pretended to become immediately absorbed in it, settling back in his chair with an air of patient but irrevocable finality. Mrs. Bride glanced appealingly at him, but his face was stony and gave her no comfort. She sat perturbed and anxious, feeling as if something dreadful had happened. A deathlike silence ensued for perhaps two minutes. Mrs. Bride then broke it fearfully.

"Harry," she said, "I feel perfectly dreadful—as if you were terribly angry at me. But you are not, are you?" Pause. "I did think when you first mentioned a show that it would be nice to see John Drew. I've been just crazy to see him in that new play of his, but I was not sure that—"

"Then you want to go, after all!" said her husband, laying down his paper and staring across at her mystifiedly.

"Why, I always love to go to the theater, but—"

"Then, for heaven's sake, come on and let's go!"

So they went, but neither enjoyed the play, because Harry was grumpish and his wife was hurt. On their return Harry stumbled over something in the dark hallway, and said "h—l!" and the bride's feelings gave way immediately. Then ensued their first quarrel. It is said they all go through it some time or other, generally in the early part of the married state.

About the House

St. Patrick's Day, the day when, according to the old weather prophets, the warm side of the stone turns up, will soon be here and everywhere you see the shamrock and the knot of green ribbon in the buttonhole. Every year the day is more generally observed. In many families one or more Irish dishes are served while some bit of green, typical of the day, is on the table; and in the evening the old Irish songs are heard in many homes.

At this season of the year the winter underwear often needs considerable mending to make it last until warm weather. In mending thin places, put a piece of cheesecloth on

Coulson's
POULTRY FOODS

Special Dry Chick Food

Makes Them Grow

COULSON'S SPECIAL DRY CHICK FOOD, during the five years it has been on the market has justly earned for itself its great reputation as a life-saver for little chicks by its special adaptation to their needs.

THE UTMOST CARE is observed in the selection of each of the dozen or more articles composing this unequalled feed; tender seeds, cracked grains blown free from dust, steel-cut oats, tiny pieces of dried meat and bone, willow and pure bone charcoal, are combined with other very necessary ingredients; every article being selected with special reference to its quality, strength, and desirability for the needs of the young chick.

FOR YOU TO BUY the many different articles composing Coulson's Special Dry Chick Food is quite impracticable; you could not be certain as to their quality for one thing, and the high cost of certain of them when purchased in small lots might lead to their being left out to the detriment of the chick.

TO MAINTAIN the high reputation of COULSON'S SPECIAL DRY CHICK FOOD, nothing is left undone to make it absolutely the best feed that can be made for the little chicks.

COULSON'S SPECIAL DRY CHICK FOOD can be fed exclusively to your little chicks for the first six weeks, at a cost of about four cents (4c) each; and what is of still greater importance, it will do all that can be done in the way of feed to bring them through that critical period of their lives in full health and vigor.

TO RAISE EVERY CHICK you hatch; to have fine, large, healthy chicks; to have chicks that will stand up and crow when eight weeks old; to raise chicks that you will be proud of, FEED COULSON'S SPECIAL DRY CHICK FOOD, THE LIFE SAVER.

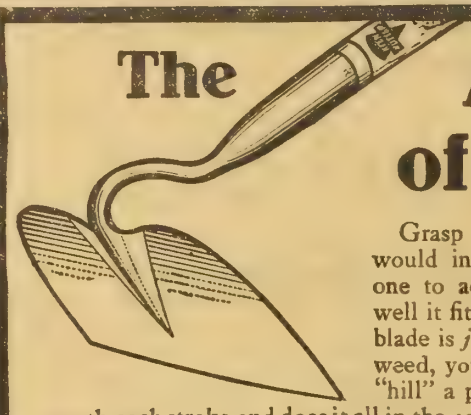
The Angle of a Hoe



Grasp a Keen Kutter Hoe as you would in the field—better yet, put one to actual service, and see how well it fits its job. The angle of the blade is *just right.* If you strike at a weed, you are sure to cut it—if you "hill" a plant it carries a full load of earth each stroke and does it all in the *easiest position* you can assume.

KEEN KUTTER

Farm and Garden Tools

are fitted by *model* and *temper* for great service and long wear. The fine oil tempering gives elasticity, power and keenness and the model "hang" and balance are just right to make the work easy.

The Keen Kutter trademark covers Forks, Hoes, Rakes, Scythes, etc., as well as all bench tools—Axes, Hammers, Saws, Planes, Adzes, Chisels, Augers, Bits, Braces, Gimlets, Bevels, Squares, Draw-knives, Gouges, etc., besides every possible tool and cutlery for the household. Look for the trademark—it guarantees *quality.* Sold for 40 years under this motto:

"The Recollection of Quality Remains Long After the Price is Forgotten."—E. C. Simmons.

Angle Lamp

The Light That Never Fails

Thousands in use all over the country. A good light is the greatest pleasure and the first necessity of every home.

The only lamp on the market that is sold under an absolute guarantee.

Remember, the light from Kerosene is the light science has agreed upon as being the purest and best, because it is soft and mellow and restful to the eyes.

Here are a few of The Angle Lamp Merits:

NO UNDER SHADOW. NO SMOKE, NO ODOR, LITTLE HEAT. GREAT ECONOMY—COST LESS TO BURN than an ordinary lamp. As easy to operate as gas or electricity, and better than either. ABSOLUTELY SAFE under all conditions. Lighted and extinguished like gas. Burned HIGH or LOW like GAS without a trace of odor. And a BRILLIANT, soft, steady, shadowless light—but this you will have to see to appreciate.

The lamp as shown in cut burns 22 hours on 3 quarts of oil.

"Johnny's crushing the tomatoes!
Flossie's spoiling all you've done!"
"Well, no matter; let 'em go it
If they're having any fun."
—Chicago Record-Herald.

Good nature is as contagious as the measles. Put on your best smile when you get up in the morning and observe how everybody will greet you with a sunny face.

the under side, then darn through it. The cheesecloth takes the strain. If you need to put on a patch first baste it on, then sew it on the machine with two rows of stitching, one a little within the other. Trim the rough edges of the patch to the outside row of stitching and the worn edge of the garment to the inside edge. In mending any kind of knit underwear be sure to make allowance for the stretching of the garments.

When the underwear is too much worn to be mended there may be parts of each garment that are good and may be made over for the little ones. Sew the seams on the machine, then press open and "catch stitch" from one side to the other. Finish the bottoms and sides of the drawers with a crochet edge. It is a simple stitch and easily done. Use knitting cotton or some of the mercerized cottons. Fasten the end of the thread, put the crochet hook through the garment, catch the thread and draw a stitch through on the hook, leaving the thread on the other side. Draw the thread through the loop on the hook. This makes the first stitch. Then put the hook through the goods, draw a stitch through; this makes two stitches on the hook; draw the thread through both stitches and repeat. Finish the tops of the drawers with muslin bands and buttonholes. The shirts are finished with the crochet edge and a simple beading crocheted around the neck to run a tape or ribbon through. The work is easily done and the small garments cost more in proportion than the large ones when bought, so the saving is considerable.

Very pretty, serviceable rugs may be made out of old ingrain carpet, and a correspondent of the American Farm World gives the following careful directions for making them:

Cut your carpet into bias strips about one and one-half inches wide. Lengthen the stitch on your sewing machine and stitch each strip through the center, joining the pieces as you go. Wind them into convenient skeins and wash in warm soap-suds. The strips will "fluff up" when dry, but the stitching will hold them together. Five and one-half pounds of "rags," thus prepared are required for a rug one and one-half yards long and twenty-eight or thirty inches wide. Now get your carpet weaver to weave it for you, using only one-third as much warp as for carpeting, and you will have a nice, durable rug, alike on both sides, and heavy enough to stay where you put it. It may be hit-or-miss, or the colors may be assorted as you cut and wind the balls. Mine is made of two kinds, light in the center with a twelve-inch border of dark at both ends. Hook in a fringe three or four inches long, or, better still, if you can obtain it, use the rug-fringe that may be purchased at any upholsterer's for fifteen to twenty-five cents a yard.

In response to a request made some weeks ago for recipes for making candied orange peel, E. N. P. sends the following.

Put the orange rinds in brine for three or four days or longer. When taken from the brine cook in fresh water until tender, then cover with cold water for a few hours. Have ready a hot syrup. Take the rinds from the cold water, place in a jar, and pour the hot syrup over them. Leave until the next day. Drain off the syrup, reheat it and add a little

HOW ONE MAN SOLD HIS FARM

A Minnesota Farmer successfully tries new long-distance plan of selling.

FOURTEEN MEN IN SIX DIFFERENT STATES WANT HIS PLACE.

Makes sale without aid of real estate agent and doesn't pay a cent commission.

Cass Co., Minnesota, (Special Correspondence)—The farmers in this section are intensely interested in a recent experience of one of their neighbors. Mr. H. St. John, who owned a farm in Cass County, has succeeded in selling it at his own price, without the help of a real estate agent and without paying a cent in commission. He could have sold the farm fourteen times over as he had that number of men after it. In the course of a conversation with your correspondent, Mr. St. John said:

"Yes, I sold my farm without any trouble and for the benefit of others who desire to sell, I don't mind telling you just how it happened. I had tried all the usual methods of selling, that is by advertising in the local papers and through local real estate men, and had about given up hope of being able to sell, when I happened to come across the advertisement of a concern known as Leonard Darbyshire, Incorporated, of Rochester, N. Y., who make a business of finding buyers for anything one wants to sell. I wrote to these people for their plan and I received a letter from Mr. Darbyshire, the President of the Corporation, together with a copy of their booklet, fully describing a new and up-to-date method of bringing buyer and seller together. Their plan looked good to me and I sent them a description of my farm which they must have sent to prospective buyers all over the country because I received no less than fourteen letters from men who wanted my place, and these letters came from Iowa, Illinois, Mississippi, Wisconsin and Nebraska, and other States outside of Minnesota. You can imagine that with such a demand I had no trouble in making a sale and I sold my farm to a man in Iowa at my own price, and what's more to the point, I didn't have to pay a cent commission to anyone. I cannot say too much in favor of the Rochester concern and I am delighted with the treatment they gave me. They did everything for me that they agreed to do and I never would have been able to sell so quickly without their assistance because it is hard to sell through an agent, and even if an agent does find a buyer, you have to pay a large amount in commission. The system of bringing buyer and seller together originated by Mr. Leonard Darbyshire, is the best I ever heard of, and he seems to be able to find buyers for all kinds of properties, no matter where they are located."

Mr. St. John's success in selling his farm was due to reading a booklet issued by Leonard Darbyshire, Inc., of Rochester, N. Y. This booklet tells of a new and successful method of finding buyers for farms and real estate, business properties, automobiles, patents and in fact almost anything salable. The Corporation issuing this book are not real estate agents and do not accept a penny in commission on sales made by their assistance. Their plan of cutting out the real estate agents has met with remarkable success, and owners throughout the country are quickly availing themselves of this opportunity to sell quickly places which for a long time remained in the hands of real estate agents, who failed to sell, for the reason that the commission which the agent placed upon the property killed the sale.

It is said that Mr. Leonard Darbyshire, the president of this concern, is doing more to assist property owners to sell than all the real estate agents in America combined, and anyone wishing to dispose of anything anywhere at any price, would do well to write to Leonard Darbyshire, President, Dept. 1034 Rochester, N. Y., giving a brief description of the property for sale, and asking him to send a free copy of his booklet explaining his new method of selling.

• • •

I have always supposed that to make a good cake you must thoroughly "beat" the eggs, but the other day in looking over an old magazine I found the following recipe for making a "firm, moist and velvety cake," It seemed most too "easy" to be good, but I tried it and it proved to be all it claimed to be:

One cup of flour, one cup of sugar, a pinch of salt and a full teaspoon of baking powder sifted together three times, a quarter of a cup of melted butter, two eggs broken into a cup and the cup filled up with milk; the whole stirred together only long enough to thoroughly mix the ingredients. This makes a good sized loaf and may be frosted any way desired. A nice chocolate cake may be evolved from the same recipe by the addition of several spoons of cocoa.

Fruit and nut "caramels" can be made without cooking, easily and quickly. Chop fine, or run through a meat grinder, nut meats, figs, dates and seeded raisins, about equal portions of each. Pack smoothly in a shallow pan and with a sharp knife cut in small squares and wrap in oil paper.

An Eastern paper gives the following as a reliable formula for making marshmallows. Dissolve half a pound of gum arabic in one pint of water, strain, add half a pound of granulated sugar (one cup), place over the fire and stir constantly until the sugar is dissolved and the mixture takes the consistency of honey. Add gradually the whites of four eggs, well beaten, stirring the mixture steadily until it will not adhere to the fingers. Pour into a pan or box slightly dusted with starch, and when cool divide into small squares.

To make "twin biscuits," roll out the biscuit dough much thinner than usual. After cutting your biscuits, brush the tops of half of them with soft butter and put the others on them sandwich fashion, pressing tightly together, then bake as usual.

Carrots are not given the consideration they merit. Not only are they palatable when well cooked, but if eaten freely are said to be a complexion beautifier. When the full flavor of the carrots is desired they should be washed carefully and boiled without scraping. After boiling, drop them in cold water and the skins will slip off as will those of beets. They may then be sliced or diced and served with melted butter or with a cream sauce. Rubbed through a sieve and added to a cream soup they will give it a delicious flavor.

I found a bagful of old stockings hanging in the closet yesterday, so last evening I "went at 'em" as the small boy of the neighborhood would put it. First I cut the feet from one pair of stockings and stitched in from the lower end about an inch or inch and a half, and wide enough to form fingers. Then I cut a hole for a thumb and had a pair of mitts and sleeve protectors in one. These I will use when planting seeds or slips, where one needs the fingers free. Another pair, I simply cut off the feet and will use the legs for sleeve protectors—not a stitch needed and several pairs of cuffs saved from smudges.

The legs of five or six stockings were cut open and then sewed up into a square and I had as good a dust cloth as I could wish for—soft and a good dust absorber. Two or three more I cut open and made a dust bag to slip over the broom. I made two pairs of mittens to use when sweeping and dusting from some old cotton socks. I cut off the feet, laid my hand in the leg and shaped a mitten, taking the ribbed part for the wrist. made the thumb from a piece cut from the top of the foot. A number of badly worn stockings I cut open and cut in four inch strips, cutting from each end until within about two inches of the middle. These I slipped into a mop stick and had a first class "dry mop" for dusting the bare floors.

If you have a seamstress coming to the house you will save time and money and temper if you will see that the machine is cleaned and oiled and in perfect repair. Have plenty of needles and thread and all the little things that will be wanted. Have some way of quickly heating an iron.

UNCLE ISAAC'S OPINION.

People have been recommended to follow the example of the ant and learn wisdom from her. Now I ain't knocking on the ant. As an insect the ant sizes up pretty well, but there is nothing in most of the work of the ant that indicates that she is overburdened with brains. The ant does more useless rippin' round than any insect I happen to know of. She will dash out and grab hold of something that she thinks she wants at the house and lug it off. If she comes to a stone on the road home does she do the sensible thing and go around it? No, she climbs over. She sweats and tugs and falls off a time or two and then spits on her hands and goes at it again and finally gets that thing home and then finds when she gets there that she had no use for it.

Want a Telephone?

If you do you can get it. If you are anxious to get into closer touch with your friends, with the family doctor, with the store, with the post office, or with the cotton buyer, you can do it with a telephone at hand. If you want to make the farm a more livable place, if you want to protect your home, you can do it by installing a telephone.

If you will cut out this advertisement, write your name and address on the margin and mail it to-day to our nearest house, we will send you at once a copy of our Free Bulletin No. 71 on

"How to Build Rural Telephone Lines"

This Bulletin explains clearly how a rural telephone system is built and operated, and it also contains full information as to costs.

In a Farmer's Mutual Company a few day's labor and a cash investment of about $25. per subscriber, will purchase all material and build an absolutely standard system.

A Rural Telephone is an investment, not an expense. The telephone which enables you to sell ten bales of cotton at ½ cent per pound more than the traveling buyer offers you, has paid for its entire cost. If you have some hay down all ready to go in, it is worth something to have a telephone with which to call on Neighbor Smith "for a lift" before the storm breaks.

The Rural Telephone pays for itself each year and we have brought the initial cost within the reach of every farmer. Present prices are especially favorable and thousands of Farmers' Mutual Companies are now organizing so as to build their lines this Spring. **Write us to-day.**

WESTERN ELECTRIC COMPANY

Southern Offices: Atlanta, Cincinnati, Dallas, Indianapolis, Kansas City, Portsmouth, Saint Louis, Savannah

The world's oldest and largest telephone manufacturer. There are over 4,000,000 Western Electric Telephones in use in the United States to-day.

Rural Telephones a specialty

Northern and Western Offices: Boston, Chicago, Denver, Los Angeles, New York, Omaha, Philadelphia, Pittsburg, Saint Paul, Salt Lake City, San Francisco, Seattle

Hay.

Receipts of hay for the past week have been considerably heavier than we have been receiving for some little time past, the total amounting to 3250 tons compared with 2300 last week. However, the demand for hay continues quite active and we can report no material decline in prices, although during the last few days there has been a trifle weaker tone to the market. From our knowledge of the situation we do not believe that receipts will continue as heavy but are very much inclined to believe that we will see a material falling off and a consequent firmer tone to the market.

Country business in hay continues very active and as the demand outside of San Francisco is principally for the better grades.

Alfalfa has been arriving rather sparingly but the demand by reason of the good weather and plentiful grass supply, has fallen off considerably and therefore we have to quote a trifle lower price on same.

Choice wheat hay	.23.00@25.00

Citrus Market

LOS ANGELES, March 10, 1909.

The extremely heavy shipments following the storm of early February demoralized the market that the effect still remains. It has not resulted in a serious slump but about 15 to 20 cents has been knocked off the profit end of every box. An effort is being made to slow up shipments and in fact it is being done. There is yet a couple of months to dispose of navels and nearly one-half the crop is gone so that there need be no rush to dispose of such great quantities at once.

Lemons are stronger in market tone and it is hoped this tendency will continue for some weeks.

Shipments.

Shipments of citrus fruits to date

Cream Separators, all sizes, all prices. O. J. Weber Co., 225-227-229-231 East Sixth street, Los Angeles.

since November 1 are: Oranges 9,499 cars; Lemons 1,647, or a total of 11,146. To same date last season 9,350 oranges, and 1,576 lemons or a total of 10,926.

BOSTON, March 8.—Thirty-one cars sold, forty-nine cars on track. Weather favorable. Market remains unchanged.

A SPLENDID RECORD OF LOYAL SERVICE.

The group shown here is a most unusual one. In the center of the front row, easily distinguished by his flowing beard, sits Hon. J. M. Studebaker, President of the Studebaker Bros. Mfg. Co., and only surviving member of the famous five Studebaker brothers, and about him are grouped eighty-three employees who have been continuously in the Studebaker employ for twenty-five years or more.

Many of the men seated about Mr. Studebaker are foremen and superintendents who started in as apprentices and learned their trade from the Studebaker brothers, and they in turn, have imparted their knowledge to their shop mates and to their sons who are following in their father's footsteps. As Mr. Studebaker says, "These men are the educators in our plant, and while we have young men under their training coming along in every department, we still depend upon this advanced class to keep our product up to the highest possible standard."

CONSOLING.

"I suppose," said the minister to the widow, "that your friends have said many consoling things to you."

"Yes," she replied, "my friends have been a great help to me in my trial. They've all told me that I look just beautiful in black."—Detroit Free Press.

LEGAL NOTE.

A London city man recently wrote to a lawyer in another town asking for information touching the standing of a person there who had owed the Londoner a considerable sum of money for a long time. "What property has he that I could attach?" was one of the questions asked. The lawyer's reply was to the point. "The person to whom you refer," he wrote, "died a year ago. He has left nothing subject to attachment except a widow."—Punch.

IN THE NEW.

"Papa," inquired little May, after Sunday school, "was George Washington an Israelite?"

Before her father could answer this somewhat unexpected question, May's six-year-old brother broke in.

"Why, May, I'm 'shamed of your ign'ance! George Washington is in the New Testament, not the Old."—Woman's Home Companion.

OYSTER SHELL.

Croley's granulated hard eastern oyster shell made from clear fresh selected shells that have not been boiled or roasted, sweeten the crop and preserve health and should be kept before the fowls continually. **Oyster Shell** does not take the place of grit, but is necessary for the lime supply of egg shells and feathers and often prevents the laying of soft-shelled eggs. Croley's Hard Eastern Oyster Shell is ground and graded into four sizes. The Fine Granulated Size (about the size of wheat) is the popular size because it is ready for work the moment it enters into the hen's crop and is easily assimilated.

One pound of Croley's Hard Eastern Oyster Shell will supply lime for about seven dozen egg shells. The Oyster Shell flour is excellent for making up balanced rations. On the basis of 1 cent per pound as the value of grains and mill feeds, one pound of Hard Eastern Oyster Shell is worth about 3 cents per pound to the poultry feeder, because these shells directly supply the lime and allow the grain, etc., to be more thoroughly assimilated and converted into eggs and flesh.

The Smooth Running, Noiseless Pomona Deep Well Pump

It is thirty to fifty per cent more efficient than any centrifugal pump ever made. No high speed bearings to cut out. All breakages and rod troubles eliminated.

This is the only pump you can afford to buy if you consider your own interests. Hundreds of satisfied users testify to this.

Used by the best water companies who know what a good pump is.

Send for a catalog or what is better come to POMONA and let us show you some of these plants in operation.

POMONA MANUFACTURING CO.
POMONA, CALIFORNIA

THE Latest Deep Well Turbine Pump

Guaranteed to deliver from 100 gallons per minute upwards, depending on the diameter and capacity of well, from a depth of 50 to 300 feet below the surface. Can be either belt driven or direct connected to electric motor as occasion requires.

Write for Catalogue 46B.

A deep well pump that has no valves or plungers to wear or get out of order, no gears, consequently no noise or breaking of teeth.

Compact, durable, always primed and ready to operate, constant flow, hence increased capacity of well.

This type of pump is fast taking the place of Vertical Steam, Deep well Plunger and Propeller Pumps.

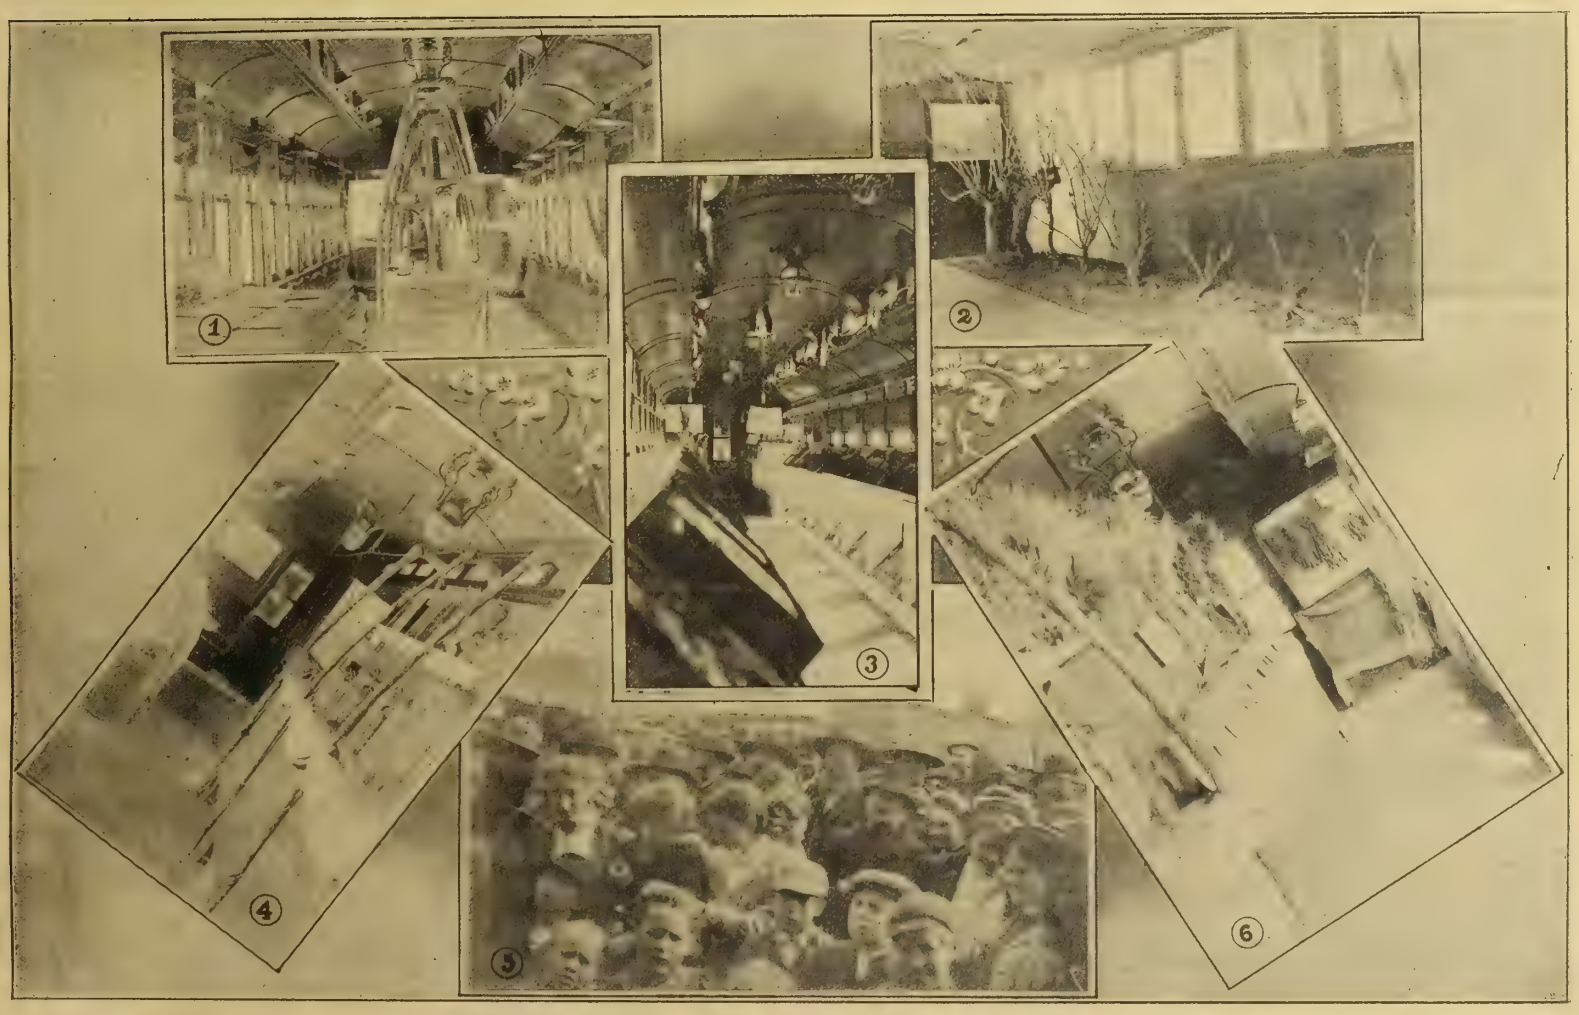
Demonstration Train--Institute on Wheels

Observations by the Associate Editor After a Few Days With the Demonstration Train. Exhibition Cars Contain Much That Is Instructive to All.



1. Scene in University Car showing plants having various diseases. In center of car exhibits of veterinary division showing tuberculous tissues. 2. Vine pruning exhibit with photos in background showing various forms of pruning. 3. State Horticultural Commission showing exhibits arranged in two decks, one near the floor, the other higher, also hundreds of exhibits in jars above the windows. 4. Veterinary and sanitary milk exhibit. 5. Crowd listening to address of President Wheeler. This photo was taken at Selma in the San Joaquin valley. 6. Cereal exhibit. Note in background new types of alfalfa. The shortest one of these is the ordinary alfalfa as now generally grown. The longest one is the new Arabian alfalfa. These exhibits were grown on fields which were cut close on the first of November. On the first of January, with treatment the same in each case, results shown were secured.

"THIS is a glorified Institute."

We were all jarred out of our revery into which we had fallen as we sipped our "small black" after a delightful luncheon in the diner of the Southern Pacific Demonstration Train. We were passing through the upper end of the beautiful San Gabriel valley. Green fields and blossoming trees in the foreground, snow-capped Sierra Madres, with "Old Baldy" as captain of the host, in the background. Over all the shimmer and sunshine of a perfect, an absolutely perfect California day.

I say we were "jarred," yet the remark was not intended as a rudeness; quite the reverse, for Mrs. Sherman, who made it, knows no rudeness. But because of her enthusiasm over good deeds done by the Demonstration Train force in "Blessing with light," could not repress "This is a glorified Institute."

The Farmers Institute is of conparatively recent birth. It is usually under the management of the Director of the Experiment Stations of each state. In this state Prof. E. J. Wickson is the director. California has two circuits or divisions in the work, Northern and Central California, in charge of Prof. W. T. Clarke, superintendent

(Continued on page 314.)

HEELS UP-HEAD DOWN

29 Yrs

There are some mighty funny things about common "bucket bowl" cream separators. One is that the bowls used in them actually run better when turned heavy end **down**-heels up, head down, as you might say.

Prove it? Why, we knew it ten years ago, and have been proving it by building Tubulars with bowls rung heavy end **down** ever since.

But we have just proved it again—this time in a very simple and practical way with a **"bucket bowl" itself.** We took a common, disc filled "bucket bowl" machine—the sort with the bowl set heavy end **up** and fed through the **top.** The machine **looked** all right, but the bowl had the "shakes" so bad—that is, it trembled, leaned and strained against its bearings so hard—that we could not run it over 6,000 revolutions per minute, though it was supposed to run 8,000 in every day use.

You see, a separator bowl set heavy end **up** is always top heavy, always leans sidewise, even though the eye can't detect it, and consequently always trembles in its bearings. These tremblings gradually increase until they wear the bearings, shake them loose, bend the spindle and create so much friction that it acts like a brake and prevents getting up speed. That was the trouble with this disc filled "bucket bowl" we are talking about.

When we found this "bucket bowl" would **not** run in its **own** machine, we took it out, cut a thread on the bottom of the spindle, and hung it, heavy end **down** in a **Sharples Tubular** Cream Separator, just as we would a bowl of our own. You should have seen it run then. **No trouble at all** to run it 8,000 revolutions per minute. We easily ran it 12,000.

Could you ask any better proof that common "bucket bowl" separators, with bowls set heavy end **up** and fed through the **top** are built all wrong? Or better proof that the **suspended** bowl and bottom feed used **only in Sharples Machine** is the right way to build a cream separator?

Tubulars are built in the world's biggest, best equipped separator factory. 1908 sales way ahead of 1907—out of sight of any competitor, if not all competitors combined. The additional good points of our 1909 Tubular "A" are making 1909 better yet.

Get our catalog 260 and then you'll know all about it—you'll be on the safe side.

The many exclusive advantages of the 1909 Sharples Tubular "A" cream separators are possible because only Sharples Separators have suspended bowl and bottom feed. This makes dairy Tubular bowls the lightest and simplest known, yet gives them twice the skimming power of common bowls. Also permits a low supply can that need not be lifted off to remove the bowl; wholly enclosed, self oiling gears; a single frictionless ball bearing from which hangs the bowl; a crank set just right for easy turning; a plumb bob for quickly leveling the separator.

Methods of Plowing the Orchard

A Series of Answers to Questions on Orchard Plowing, Cover Crops and Fertilizing, Written by Orchardists From Various Parts of the State.

THERE are but few orchardists who do not believe in plowing. There are less than there were a few years ago. As to deep and shallow plowing there is less unanimity of expression. One of the Cultivator's most valued writers, Mr. J. W. Mills, believes in shallow culture. He has often given reasons for the faith that is in him in this paper. In the main his position is that the sun's warmth and the air acting on the upper portion of soil make it more available and that if permitted the roots will fill the ground near the surface and appropriate the needed elements better than if forced by deep culture into lower colder soils.

We believe there are more who believe that a tree of more regular growth is secured and one of stronger root system encouraged by the deep culture plan.

However, the purpose of this article is not to express opinion so much as to give place for responses by representative orchardists as to methods which they follow. To secure this expression a letter was sent to each with the following questions:

The Questions.

The Cultivator repeatedly has the question presented by its subscribers, "Which is better, deep or shallow plowing in orchards?" Opinions seem to differ most decidedly, so we are going to take the liberty of asking a number of representative orchardists for their opinion in the matter. If you can control your time so as to give a few moments to it will you give your opinion as to the following questions:

(1) Do you grow green manure crops?

(2) Do you disk or plow them in?

(3) If you plow, how do you force all of the green stuff under?

(4) Do you plow only once during the season, or do you cross plow?

(5) How deep do you plow?

(6) Do you consider deep plowing as injurious in any way to roots of trees?

(7) Do you plow deeper with deciduous trees than in the orange orchards?

(8) Do you follow immediately so as to pack the soil, or do you allow it to lie up loose for a time so as to permit air to enter?

(9) Do you plow so as to leave dead-furrow or ridge or do you have a plan by which that is avoided?

(10) Do you plan to reach under the branches and close to the trunk or leave that for hand work?

(11) Do you ever subsoil? If so, at what time of year?

(12) What are the advantages of plowing?

We will not repeat the questions every time, but will give number to answer when it needs the question to understand the answer.

The first communication is by

* * * *

Mr. C. E. Rumsey of Riverside.

1. I grow green crops—vetch.
2. I plow.
3. If any trouble, hang a chain on.
4. We plow once and later disk across.
5. We try for eight or nine inches.
6. I do not. I have subsoiled 17 inches deep, ten feet from tree, and by mistake they ran it on other side (one row) six feet from tree, 17 inches deep. I was half sick, expecting trees to go back; all my old trees are lettered and numbered so there could be no mistake. To my surprise, we could never tell in leaf, blossom or fruit that it had been done. Since then I have had no fear. It was done in February, March or April; I can't tell which.
7. Have no deciduous trees.
8. We harrow it once; soil should be packed to rot the green crop.
9. We use disk plows; they slice a root if they strike one and do not pull it loose as mould board plow does. We throw all one way between each row; it does not make much dead furrow and we run right along that with disk harrow, which goes close to the trees. We skip a row in turning sometimes if it makes better work—i. e., plow alternate rows.
10. Answered above; the dirt is thrown over close to one row and we disk harrow on the other.
11. No, not lately.
12. Some orchards are never plowed and seem to do well. On my land when not plowed the roots got so near the surface we could not irrigate well and were forced to plow out roots by the wagon-load. No bad results followed. Since then decided we did not want any roots above eight inches.

I believe our orchards need cover crops, and that forces plowing. I only tell you my practice. I put on just as much barn yard manure in August as before, seven or eight feet to old trees, then sow vetch in September, plow under in February and add 10 to 15 pounds balanced commercial fertilizer for old trees. Even with the cover crop I do not find I fertilize too much; would do more rather than less. For two years crop on old trees has been light (my first experience). It is either the too cold springs, or I have not fertilized enough. I have proved that fertilizing at these times affects the next crop and that is all I care for. Other times may do as well, I only give my experience.—C. E. Rumsey.

* * * *

Mr. E. D. Neff, Pasadena.

Replying to your inquiry for my experience in sub-soiling, I beg to state that my conclusions are as follows, after ten years' practice:

Sub-soiling, when done with a sub-soiler having a wedge-shaped horizontal foot, is very beneficial in any soil, but particularly so where the loam is underlaid by clay or hard-pan, as is the case in most of our mesa land. The wedge-shaped foot in hard-pan lifts and cracks the clay for ten to twenty inches on each side of it. It is therefore unnecessary to make the trips nearer than three or four feet. The greatest benefit derived from sub-soiling, aside from the aeration of the soil, is in the storage of water. An irrigating stream that on regularly cultivated soil would take twenty-four hours to run 600 feet, would require four or five times as long after the ground had been sub-soiled, owing to the immense amount of water absorbed. The value of this in preparing for a dry-season is inestimable.

The depth to which a sub-soiler should be run must be governed by the character of the soil. I think that tree roots within six or seven inches of the surface are of no particular value, owing to their tendency to dry out. In a well established grove or orchard, sub-soiling must be done with great caution, the owner using his own judgment about the number of roots which it is safe to cut. The safest plan is to run the sub-soiler down about four row of trees at varying depths and distances from them and note carefully the results.

In setting out young trees, two or three trips of a sub-soiler in the line of proposed planting would insure a splendid start for the trees.—E. D. Neff.

* * * *

Mr. S. J. Beals, Orange.

I have looked upon myself, and still do, as a learner on this subject and kindred subjects, rather than as a teacher; still, as you have asked for my opinion in the matter. I will give it for what it may be worth and rather as suggesting topics for discussion and investigation, than as an attempt to state final conclusions, though it may take the form of conclusions, as far as my present knowledge on the subject extends.

First, as to green manure crop: In my opinion the value of such a crop can hardly be doubted. It grows almost entirely from the air and water, taking almost no soil substance, or at least but little, and what it does take, it returns to the soil again when it decays. The air supply is unlimited, and the water of the season of the year when the crop is growing, is almost always at hand in abundance, usually from the rainfall. The cover crop, especially if it is composed of one of the legumes, or nitrogenous producing plants, is valuable for two reasons: first, because when it rots in the soil it forms humus, or vegetable mould; and second, because it has the capacity of taking free nitrogen from the air and fixing it in the root nodules, in a form available as plant food. The great value of such a crop would seem to be fully established, as far as annual crops are concerned, from long ages of experience, and if this is true in regard to crops of grain, it would seem that it must be true that such crops tend to improve soil conditions generally, and therefore must be of benefit to citrus and other trees. It is certainly the cheapest form of fertilization and is within the reach of all.

Second, as to plowing under: Assuming, then, that during the fall and winter months, a heavy crop of vetch, fenugreek, burr clover, or similar green manure crop, has been grown, how shall the greatest benefit from such crop be secured.

If it is allowed to die down and decay on the top of the ground, a part of this benefit would no doubt be obtained, but hardly the full benefit. The roots, with the nitrogenous nodules, would decay in the soil, and the decay of the plants above the ground would produce a certain amount of humus, but very much less than would be the case if the plant is turned under the soil and allowed to rot with the air excluded or partially excluded

It is necessary, moreover, to get the rank growth out of the way, in order to prepare the soil by cultivation for the irrigation that will soon be necessary. I would advocate then plowing the crop under, at least in the spaces that will be used for irrigation, say in the space running east and west. A disk plow will probably turn the crop under better than it can be done with the ordinary plow, but either can be used, in most cases.

As to sub-soiling: I am disposed to think that this can perhaps be done with advantage if confined to the center of the spaces between the trees only. I do not believe that it will do to cut too many of the roots of the trees, as will be the case if sub-soiling is done at all close to them.

PLOWING THE ORCHARD.

(Continued from Page 307.)

This objection can also be urged against deep plowing.

As to plowing on both sides of the trees, that is, in the spaces say north and south, as well as east and west, I am in doubt, the question being whether it is not better to leave this space for the roots of the trees to have full opportunity to develop near the surface without this annual tearing up.

I doubt if irrigation water goes very deep, and if this is the case, the roots must seek the water near the surface of the ground, and if we refuse the tree the opportunity it seeks of coming near the surface to get this water, we may be doing it an injury rather than a benefit. I know it is usual, perhaps almost universal, to plow, or at least cultivate through the summer, on both sides of the tree, but I am disposed to think that the question is an open one, if the spaces are covered with a heavy growth of cover crop, that will, in great measure, protect the soil from the sun for a great part or all of the dry season.

The above only attempts to discuss some of the subjects mentioned in your letter of the 24th ult., but the other questions will no doubt be fully covered by others.—S. J. Beals.

* * *

Mr. Frank L. Palmer, North Pomona.

I have received your list of questions relative to orchard plowing, and will answer them somewhat categorically, but cannot at this time undertake to enter into a discussion of the subject:

1:—Yes.

2:—I plow them under.

3:—We find that a disk plow handles a vetch crop very nicely.

4:—Where we have grown a cover crop we either cross plow or cross the orchard with a disk harrow, depending on existing conditions.

5:—About six inches.

6:—Yes, when deep enough to destroy the roots.

8:—After turning under a green crop we harrow the ground lightly, desiring to encourage a quick decay of the green stuff turned under.

9:—We follow what some people call "to and from" plowing. By beginning next the tree row and plowing toward the trees, and returning in the next middle throwing the earth toward the same row of trees, it leaves the first middle with the earth thrown in one direction and the next middle with the earth thrown in the opposite direction. The surface as a whole is left quite smooth, particularly if the plowing is shallow next the trees.

10:—Our trees grow low to the ground, and it is impracticable to do any plowing "close to the trunk."

11:—I do not practice sub-soiling, but have done it at times when necessary to break up artificial hard-pan.

12:—If this is an abstract question, it might be said that the advantages are many. Plowing improves the physical condition of the soil, permits an aeration of the soil, promotes nitrification in the soil; is an efficient means of pulverizing the soil when needed; is a means of turning under weeds or cover crops, as the case may be, etc., etc. I infer, however, that the real object of the question is to bring out discussion from those who do not advocate orchard plowing; and I imagine that on light soils, well drained, some orchardists consider plowing superfluous.—Frank S. Palmer.

* * *

Mr. C. H. Rodgers, Watsonville.

1:—Yes.

2:—Plow.

3:—Rolling coulter and chain.

4:—Once.

5:—Six to eight inches.

6:—If deep plowing has been practiced since the trees were planted, no. If shallow plowing has been the rule, then deep plowing will prove injurious temporarily.

7:—Do not raise oranges commercially.

8:—All depends upon season and nature of soil. If late in season or if soil is tough then soil should be smoothed down, but never packed.

9:—By plowing two rows of trees in one "land," there will be no ridges or dead-furrows between rows.

10:—I train my trees high enough so that all the land may be turned with the plow.

11:—(a) I never sub-soil old orchards, but sometimes sub-soil young orchards. (b) In winter.

12:—Turning under and covering vegetation, loosening the soil for the conservation of moisture and to give easy access to air.

It must be understood that soils in different localities and the various soils in the same locality often require different treatment. While in some sections of the state, orchard cultivation may be successfully carried on with cultivator and disk, in Pajaro valley the plow is an absolute necessity.—C. H. Rodgers.

* * *

Mr. B. E. Hutchinson, Fowler.

1:—I do not grow green manure crops but use all the fresh stable manure I can get.

2:—I never disk; I always plow; my land is sandy.

3:—I have no trouble in covering all growth with the plows and I cultivate and harrow after each plowing.

4:—I always plow from three to five times per season.

5:—I plow as deep as a good team can do it, from eight to ten inches.

6:—If roots go downward as they should, deep plowing will do no harm.

7:—I plow all trees alike.

8:—I cross cultivate immediately after plowing and then harrow thoroughly so as to hold all moisture possible.

9:—I plow so as to keep the land as level as possible; don't want any ridges.

10:—I plan to plow as close to trees as possible, but always hoe or shovel thoroughly wherever the plow does not cover all the surface. Never leave any weeds.

11:—I never sub-soil, except when preparing to plant trees; in this way the roots will naturally grow downward if you irrigate heavily.

12:—The advantage of plowing is principally for holding the moisture, covering the weeds or cover crops, etc. The cover crop or plenty of fresh manure is very necessary, as the more humus you can get into the soil the better. Don't ever try to cheat or fool your land by neglecting it, for you are fooling yourself instead of the land.—B. E. Hutchinson.

* * *

Mr. Horace G. Keesling, San Jose.

1:—In a way I grow green manure

or cover crops in my orchards by encouraging such volunteer growth as burr clover and alfillarie to grow as large and thick as possible. I believe that it will pay fruit growers to sow for green manure crops if the spontaneous growth is not sufficiently heavy.

2:—I plow.

3:—By using a rolling coulter and a chain any thickness or height of green crops may be turned under in good shape.

4:—I plow only once.

5:—About five inches.

6:—No.

7:—Have had no experience with orange trees in a large way.

8:—The treatment of the soil after plowing is governed almost entirely by the condition of the soil and the weather. If the soil is well filled with moisture and more rain is coming, it is best to leave the soil for a time. I do not like the expression "pack the soil." It is not good for any soil to ever be "packed" and heavy soils are greatly injured when worked so wet as to become packed. We plow our orchards to loosen the soil, turn under and save the green crops and finally work it down so that it is in a condition to admit some air, but not so much as to aid in evaporating the moisture that is needed for the trees' growth. As different soils require different treatment, no set rules may be made to govern all sections. The proper treatment of the soil in an orchard must be left to the intelligence and experience of its owner.

9:—I leave a dead-furrow in the tree rows one year and in the center of the space the next year. However, these dead-furrows are cut up by the disks before we are through cultivating for the summer. I prefer the solid bladed disks. The plow, disk, harrow and clod crusher and leveler constitute all our tools for working the soil.

10:—Yes. The very little space not turned by the plow is broken up when loking for borers.

11:—No.

12:—I know of no way of beginning the annual battle with the soil in our orchards better than by properly and neatly turning it bottom side up. The green crops are then out of sight and should be kept so. I have experimented largely with disks but have no desire to use them again in lieu of the plow.—Horace G. Keesling.

• • •

Mrs. M. E. Sherman, Fresno.

1:—Yes. The best practice that we know of in securing humus in the soil is by growing green crops. We grow more of these in the summer in the orchard each year.

2:—The use of the disks with us is to chop up a crop that is too tall to turn under readily if left as it is. Take one of these very heavy crops while green and run the disks sometimes both ways across it before turning it under with the plow.

3:—Readily, if disked first and the crop is turned under while in bloom. The only times we have failed have been by letting the crop mature until it seeded and not disking first to make the pieces small.

4:—When turning under a cover crop the second plowing should be held off three weeks to let the green crop rot. We plow twice always, sometimes four times; the season has more to do with it than actual rules. Twice—that is, plow and cross-plow.

5:—Six to eight inches usually at six feet from the trees and three inches closer to them.

6:—Not if it has always been done. The idea is to force the roots down where they belong from the beginning. Trees that have many surface roots suffer from drought and are not as healthy as those that have the roots better covered. If I had a shallow-rooted orchard or vineyard I should at once begin to deepen the plowing, taking it at least two inches deep the first year and doing this until there was a clear ten inches of mulch soil over the roots.

7:—Walnuts I never have handled. Peaches, plums, olives and oranges are all plowed alike with us. Our experience in oranges is very limited, however.

8:—Harrow the land at once; the harrows are never half a day behind the plow; this conserves the moisture with us better than to let the soil remain cupped and with air space under it.

9:—The use of the revolving harrow throws enough dirt to the dead-

(Continued on Page 324.)

DEAD CITRUS WOOD

Is more or less prevalent in every orange and lemon grove, i. e., trees that are unprofitable. How many such have you in your orchard? Would it not pay you to put paying trees in their stead?

Your Home Grounds

Should contain at least a few trees of the better varieties of oranges and lemons. For this purpose we have some exceptionally fine trees to offer, being grown as specimens. Possibly you would like to plant a few citrus trees about your home this season. If so, will you do us the favor to correspond with us about it?

TREE TANGLEFOOT

A Sticky Preparation Applied Directly to the Bark of the Trees

Will not injure trees. A band 5 inches wide and 1-16-inch thick cannot be crossed by any climbing insect pest. Remains sticky five to ten times as long as any other known substance. You can test it at slight expense, as no apparatus is required. Used by the carload in New England against the Gypsy and Brown-Tail moths. In California it preserves prune orchards from the Canker Worm. Wherever the Gypsy or Brown-tail Moths, Tussock Moths, Fall or Spring Canker Worm or Web Worm appear TREE TANGLEFOOT is of great value, and should be used when the caterpillars begin to crawl w hilh ey are very young.

Price, 1-lb. cans, 30c; 3-lb. cans, 85c; 10-lb. cans, $2.65; 20-lb. cans, $4.80. The only safe and effective banding preparation. Send for testimonials.

WALNUT GROWERS ORGANIZE.

THE walnut growers of Southern California have been much disappointed at the returns from this past year's output of approximately 800 cars of walnuts. Notwithstanding an organization which has endeavored to maintain a living price, the market this season was knocked all to pieces, some growers receiving very indifferent returns. The organization has been a very loose one, there being 17 individual associations in the southern part of the state. These associations dealing almost entirely independent of each other, and yet trying to agree on a price which shall generally prevail. Year before last with a smaller output, fair results were obtained. The results of this past year were such however, that the better informed saw that it was necessary to form an association more along the lines of the Citrus Fruit Growers Exchange.

The leading growers met in Los Angeles last week, and decided definitely on an incorporation under the new law, passed by the present State Legislature.

It is probable that the marketing during the coming season will be through the hands of brokers as heretofore, but instead of each separate association marketing its fruit, its duties will be taken up with the bleaching, sacking and shipping, while a central organization or its selling agent will have entire charge of the business end.

Of the 17 associations, 12 have already determined to join the new organization. There will be 34 directors elected by the various associations.

It it now thought that of the 850 carloads which Southern California will produce during the coming year, 700 still will be in this organization.

ADVERTISE THE RAISINS.

The raisin men are awakening to the worth of advertising. Another year will see better conception all over the East of the worth of the raisin as food. The Fresno Republican recently offered prizes for best article on raisins, and from the first-prize article we clip the following:

"In times long past no feast upon the tables of the rich and the great of earth was complete without the raisins of Spain, and it was alone in Spain that the raisin became an article of general consumption and entered largely into the diet of the people. In other countries raisins were a luxury of the rich; in Spain, they were upon the tables of the people, as the potato in Ireland and rice in the Orient. With black bread and herbs they were the food of the peasant, maid and matron, and scarcely less were they esteemed by the princess who dined in royal state."

To the people of our up-to-date age and country the name of health food signifies a preparation of pre-digested cereals or specially prepared food for invalids. The people of Spain for the passing centuries have had in raisins a greater health food than the ingenuity of man has ever compounded.

Raisins not only possess the food qualities that nourish the body and sustain life, but they are perfect eliminants of the harmful acids that are left in the human system through the use of foods that clog and impede the organs of digestion and assimilation. For this reason the free use of raisins purifies and enriches the blood and creates brawn and beauty.

At the present time this truth about raisins is known to comparatively few. In the United States, with the exception of some of the enlightened people of California, the raisin is still a luxury used frequently with nuts and black coffee after dinner or in the plum pudding at rare intervals. As a food, used daily and plentifully in the various ways in which they are a delight to the palate and a stimulant to the digestive system, the value of raisins is still practically unknown.

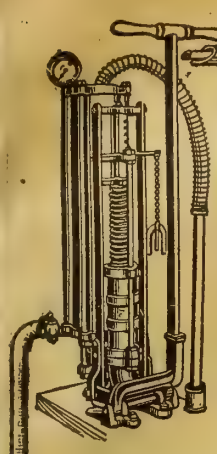
It is putting it none too strongly to say that this ignorance is a widespread misfortune. When Spain was the only producer of raisins it was excusable ignorance, for the supply was limited and the means of distribution inadequate. But now, when the interior valleys of California supply raisins of surpassing quality and in prodigal abundance for all the Western world, they should be found daily upon every table, in the form and perfection of flavor in which they come from the vineyard and in the varied forms in which they may be served, cooked and uncooked, to add variety and pleasure to the menu and health to the consumer.

The raisins of California are produced under conditions and amid environment that appeals alike to the imagination and the practical approval of the discerning. Here are beauty and utility united in perfection. The lofty Sierras, eternally snow-crowned and towering above the slumbering valley until their white pinnacles are lost amid the blue vaults of space, present to man at once a picture of incomparable grandeur and a beneficent bounty of Nature that has but few counterparts in the world. From the snow fields and glacial ice deposits of these frigid heights come the exhaustless streams of pure water that make green and fruitful the semi-tropic plains below.

Amid such scenes of entrancing beauty, in an atmosphere purified by countless days of sunshine and fragrant with ever-blooming flowers are California raisins produced!

Is it any cause for wonder that the blessed union of such fertile land with waters so bountiful and pure should produce a marvelous vintage, or that into the perfect fruit there should be distilled those elements from Nature's laboratory that sustain, prolong and beautify human life?

The well-grown and well-cured California raisin is the most delicious and the most healthful fruit bestowed upon mankind. It is only necessary that its true value as a food become widely known. Sugar in moderate quantities is required by the human system. This is especially true of growing children. The sugar of the grape, matured and perfected in the raisin is, by scientific analysis and experience, superior to all other. It is far more healthful and nourishing than any kind of confectionery. The housewife who supplies the children liberally with seeded or seedless raisins and all the family with raisins in the various forms in which they are so appetizing, will be amply [illegible] her wisdom by the pl[illegible] health of those who h[illegible] under her care.



Saves One-Third the Labor

Wouldn't you like to cut your labor expense an even third? You can do it on your spraying —and this advertisement tells you how. What's more, the work will be done more quickly and better. Use

Bean Magic Spray Pumps

The Bean patent spring (shown in the cut), divides the work; the operator does half at each stroke of the handle, and works against but half the pressure indicated on the gauge. Bean Magics are built in two sizes; both have non-clogging ball valves, porcelained cylinders, and other exclusive Bean features. They're the easiest running, least troublesome pumps on the market.

Our illustrated catalog No. 21 describes ten sizes of hand pumps, and contains much valuable spray information and formulas. Catalog No. 22 describes Power Sprayers. Both books sent free. Write for our special offer; mention number of acres and kind of fruit.

FUTURE OF THE PRUNE BUSINESS.

THOSE familiar with the market reports will remember that in the autumn of 1908 the sheep men of Wyoming and Idaho were greatly discouraged. As the shearing season advanced the wool passed into the hands of Eastern commission men at prices which indicated almost a total failure of the market. Small councils took the first remedial measure by meeting to discuss the subject of organization. Then larger ones followed, and on January 16, 1909, a defensive trust was formulated at an all-Western conference of sheep men, held at Pocatello, Idaho. Some time previous to this a conference had been held at Cheyenne, Wyoming, a month later another at Salt Lake City, and in November a number of State meetings at different places. These conferences uncovered the cause of the sheep men's distress. They were at the mercy of a buying trust. At the close of the shearing season the one thing needful was money, and not having it the trust took advantage of the situation and pressed the price down to starvation. Thus the sheep man was squeezed. How to meet this condition the conferences sought to learn, and they learned. "Fight the trust with a bigger trust" was the slogan, and it resulted in the establishment of "The National Wool Warehouse and Storage Company," a corporation, as one paper says, "that bids fair to revolutionize the methods of wool traffic within the season now immediately approaching. It promises to shake off with one movement the whole tribe of buyers from the East who have flourished among the flocks ever since Western wool began to seek an Eastern market, and to substitute in their stead at Chicago a wool depot where each year there will be shipped 150,000,000 pounds of wool, there to be offered, not to commission men, but to big manufacturers direct."

So much for the intelligence of the wool-grower. It is an old saying that the wise man is not he who never makes a mistake, but he who never makes the same mistake twice. How about our prune-growers? They repeat the mistake from year to year of putting into the hands of the packer and the Eastern commission men the crops which should give them a profit for their labor and investment. In the face of a market drifting from bad to worse, no effort is made even so much as to intelligently inquire into the cause of it all. Simply because one combination failed of all the good things it seemed to promise, the grower, discouraged and heartsick, supinely falls upon his elbows and does nothing. Now this indifference, if continued, can only result in the complete annihilation of an industry, which, if conducted in the same spirit of unity which characterizes the conduct of some of the great legitimate trusts, would be very profitable.

Perhaps there is not a grower in this county who does not know that he is being either deliberately robbed, or skilfully "jobbed," by someone. A child of six years could not be so obtuse as not to know that if the consumer pays about seven times as much per pound for his prunes as the grower receives there is something wrong, and he would at once ask: "Who pockets the difference?" This solved and corrected, and the grower will come into his own.

But how are we to go about it? Go ask the sheep man who has just extricated himself from impending bankruptcy; who has established his own warehouse as a means of getting closer to the consumer, and who in a single step has gone over the heads of a multitude of middlemen who for years have waxed fat on commissions and percentages which belong to the sheep man and to no one else.

If the prune-growers of the Pacific Coast would but employ some brainy business leader to organize them and their business it would pay them an hundredfold, even though the fee of such a man were fixed at $100,000. There is no other way by which this vast business can be saved. In this county alone the land under prunes represents a tremendous investment upon which thousands depend for sustenance. To let it drift into decline and death is criminal, and yet that is inevitable unless something is done, and soon, to prevent it. Have we a leader large enough and honest enough to undertake this task, and have we a sufficient number of growers willing to be saved if it be shown that they can be saved?—San Jose Mercury.

HOME CANNING FOR MARKET.

It is a very significant fact that the idea of saving the surplus by home canning has in many cases proved practicable.

Cheap outfits, which make it possible to adopt in a small way the methods of the cannery, are now in use by many a farmer and gardener. The results are satisfactory, because there is a ready sale for fruits and vegetables put up by persons known to be careful and cleanly. The sale of these home products must perforce be in competition with factory goods, but there is an increasing class of buyers who look to quality, rather than price.

Let the work be done as nicely as for the home table and the market for the output is secured.

The weak point in the plans of the gardener and fruit grower is this: Just when he has a good crop in any line there is apt to be a glut, and much of it goes for the bare cost of gathering.

At this very point the home canning plan comes to his relief. He stops the further demoralization of the market, and assures himself a paying price for his surplus.

Perhaps there is more going to waste than you realize. A bushel of tomatoes will make twenty three-pound cans. A bushel of raspberries or blackberries will make over thirty cans. Strawberries will be a little less. Apples will yield about eighteen, and peaches about twenty cans per bushel.

Figure from this how much you are losing every time there is a glut, and consider if it is not wise to save it.

WORTH SAVING.

Don't throw away the hoe with a broken handle, even if if there are only two feet of the handle left. Instead, take it to a blacksmith shop and have the hoe straightened out on a line with the handle. It would not be amiss, also, to have the hoe sharpened. You will find this useful in many ways around the chicken house, or in the garden, for digging weeds or lifting plants for repotting.

TREES

Hurry Your Order

Get your trees in the ground as soon as possible.

Season Advancing

and the rapidly decreasing stocks make it advisable for you to place your order at once.

Bedrock Prices Now

We have the largest and finest stock on the coast. Our trees are all true to name, strong and thrifty, and are properly prepared for shipping so they reach their destination in perfect condition.

Apples

Arkansas Black, Ben Davis, Gano (Black Ben Davis), Jonathan, White Winter Pearmain, Winesap, Yellow Bellflower.

Pears

Bartlett, Doyenne du Comice and Glou Morceau, the three great commercial pears, 10,000 Imported French Pear seedlings for immediate shipment. Write for prices.

Peaches and Apricots

Special prices on our Royal and Blenheim Apricots uo Myrobolan root and on the following varieties of peaches: Elberta, Lovell, McDevitt, Cling, Muir, Phillips, Runyons Orange and Sellers Orange Clings, Susquehanna, Tuscan Cling and Wheatland.

Grape Vines

We are offering big inducements on all the leading table, raisin and wine grapes. Write for our Surplus List No. 2. We will make it worth your while to figure with us.

Roses

Send us your orders and let us make a selection of roses for you. We will fill your orders with first class plants, our selection, for $1.80 per dozen.

FIGURE WHAT YOU'RE LOSING

The New York Experiment Station at Geneva, N. Y., reports that in an exhaustive experiment which covered 10 years the average "gain due to spraying potatoes" was 233 bushels per acre. How much would that amount to on your crop?—Have you ever figured it out? You can increase your crop just as much, and the increase of "one acre" will more than pay for our best sprayer. If you are tired of seeing your crop cut in half—by blight, bugs, rot, etc. Get one of our

HURST POTATO SPRAYERS

on Free Trial NO MONEY IN ADVANCE PAY AFTER IT HAS PAID FOR ITSELF

no-bank-deposit, no-strings-to-our-"free-trial." Spray first, then if you buy—pay us out of the "extra profit." These sprayers SPRAY ANYTHING, potatoes and truck, 4 to 6 rows at a time. Also first-class orchard and vineyard sprayers. "Man-Power and Horse-Power." High-pressure and perfect agitation. Vapor Spray prevents blight, scab, rot and bugs and other insects from injuring your crop. Strong and durable. Brass ball-valves, plunger, cylinder, strainer, etc. GUARANTEED 5 YEARS. Shipped direct to you at dealer's wholesale prices. We pay freight. Tell us which sprayer you are interested in and you'll get our valuable Spraying-Guide, Catalog of "all kinds" of sprayers, and our special free Sprayer offer to first in your locality this season.

Small Fruits and Vegetables

POINTERS ON GROWING ASPARAGUS.

THE first essential to the successful growing of asparagus is the selection of the soil. Since the crop is to remain in position for many years, the soil should be selected with that fact in mind. The plant is most grateful for a warm, sandy soil or a light loam, and a soil carrying much organic matter is a very desirable one for this crop. In some sections reclaimed swamp land produces abundant crops. In California thousands of acres of tule lands are devoted to the growing of asparagus. There is no danger from an over rich forcing soil for this crop, for the earlier it can be placed upon the market the better the financial returns. Moreover a first class product can only be raised on a very rich soil.

The desire of the producer to obtain green or white asparagus will decide the manner of planting. If white asparagus is desired furrows four feet apart should be cleaned out to a depth of from eight to twelve inches; but if the green shoots are the object, the crown should be set only three or four inches beneath the surface. At the outset the plants should not be too deeply covered, two inches being sufficient, but the furrows should be gradually filled as the growth increases.

A clean culture should be carried on at all times. This not only conserves moisture, but it allows the cutting to be done more expeditiously.

There is practically no soil on which asparagus grows, but what fertilizers can be applied profitably. Stable manure is used by some growers, but the great objection to its use is that it carries so many obnoxious weed seeds. On account of supplying humus there is sometimes an advantage in using manures, but since the average farm manures are low in potash and phosphoric acid, these elements should supplement the manures. Potash is a much needed element in the asparagus field, since it insures a crisp, well flavored shoot, which is firm enough to carry well. Muriate of potash is the best form to use under asparagus.

Nitrate of soda can also be used profitably, Even growers on tule lands find an advantage in using it, since it promotes an early start. From 400 to 800 lbs. per acre of a mixture analyzing nitrogen, 4 per cent phosphoric acid, 7 per cent, and potash, 9 per cent, which is a poular one, should be used, but if the simples are to be bought the following can be used per acre: 100 to 200 pounds nitrate of soda; 200 to 400 pounds phosphoric acid, and 75 to 150 pounds of muriate of potash. This material should be worked in between the rows as early in the spring as possible. To old fields an application of potash and phosphoric acid can profitably be made after the last cutting, and this followed with a liberal dressing of nitrate of soda in the spring.—D. I. Duncan.

SPRAYING.

It is especially important this month to spray or dust all the trunks, stems and branches of fruit trees, grape vines and berry plants with Bordeaux mixture in order to kill fungus and prevent leaf curl and blight; a second spraying is necessary about the time the buds start.

HEN MANURE FOR POTATOES.

A writer in Farm Poultry gives his experience with hen manure on potatoes as follows:

We took for our potato patch just one-third of an acre, and covered it broadcast with a moderate coating of hen manure that had been collected from the dropping boards. This was all the dressing the piece had. We planted our potatoes, and the following week hoed them once with a horse hoe. This is all the time or labor that was expended on the crop, except the labor of digging and picking up this fall. The crop from this one-third acre was just 150 bushels of extra large smooth potatoes, and ten bushels of small ones. The potatoes were of such excellent quality that they brought five cents per bushel more from the Boston buyer than any other potatoes in this locality. The piece used was of easy access from the free range occupied by the pullets this summer. These pullets assisted materially in the crop, as they kept the piece well "cultivated" by their scratching, and kept away or ate up all the potato bugs; we did not see a bug on the piece, and did not use an ounce of Paris green or Bordeaux mixture. The crop of (at the rate of) 480 bushels to the acre was certainly a good one, and the expense was certainly the minimum. We think it is a good illustration of the quick liberation of plant food from hen manure.

THE PROPERTIES OF VEGETABLES.

The following information regarding the properties of common vegetables may be useful to most people. Spinach has a direct effect upon the kidneys. The common dandelion, used as greens, is excellent for the same trouble. Asparagus purges the blood. Celery acts admirably upon the nervous system and is said to be a cure for rheumatism and neuralgia. Tomatoes act upon the liver. Beets and turnips are excellent appetizers. Lettuce and cucumbers are cooling in their effects upon the system. Onions, garlic, leeks, olives and shallots, all of which are similar, possess medicinal virtues of a marked character, stimulating the circulatory system, and the consequent increase of the saliva. Red onions are an excellent diuretic, and the white ones are recommended to be eaten raw as a remedy for insomnia. They are a tonic and nutritious. A soup made from onions is regarded by the French as an excellent restorative in debility of the digestive organs.

Humus in the soil is a very important part in gardening. This may be supplied in the form of well rotted manure where plenty of straw, stover and old leaves have been used in the stable for bedding.

Sunshine destroys fungous growth and should be let in through the trees and to the ground beneath.

This is a good month to get the hotbed planned for the spring work. Paint the sash and get everything in readiness.

The best time to kill weeds is when they are germinating and before they push through the ground. Frequent shallow cultivation will accomplish this.

County Control of Tree Planting on County Roads

"Beautify our roadways" should be a slogan with all well wishers of California. Shaded and beautified streets add to desirability of property, and desirability increases wealth. We are glad to give the following by the veteran tree warden of Riverside, J. H. Reed, the tree lover. Regarding him and his work the Riverside Chamber of Commerce recently passed the following resolutions:

"Resolved, That the Chamber of Commerce of Riverside recognizes in J. H. Reed, municipal tree warden, an officer whose unselfish and painstaking labors in behalf of the city have resulted in immeasurable benefits to this community.

"Resolved, That we congratulate Mayor Evans and the city administration upon being able to secure the services of a man so experienced and so well equipped for the work which he has in hand, and hereby express our most earnest hope that Mr. Reed will long be able to continue in the work which he now has in hand.

"Resolved, That we take this means of assuring Mr. Reed of our most hearty endorsement of his work and of thanking him for his labors, for which the city is able to so inadequately recompense him."

THE campaign for good roads in California, so long carried on in papers and conventions, now bids fair to materialize into real road building. Many miles of good road beds will be built in California at least, in the near future. The economy and comfort they will bring, will be exceedingly great. But the pleasure and satisfaction they may bring will not be complete till they are lined with shade trees. Plans for ornamenting these highways should go on simultaneously with those of their building.

These good roads are not being built especially for speedways for transient autoists, who simply care to get on, or who find a sort of pleasure in rapid motion, as does the child in a high-going swing or merry-go-round, regardless of discomforts and danger of the ordinary traveler. They are, or should be, mainly for the convenience and pleasure of resident people who pay the cost of their building and maintenance, those who appreciate something more than mere speed, and use the roads for business or pleasure as occasion requires.

City and County Control.

The municipal governments that build the expensive road-beds on the residence streets of our cities, leaving them, as is so often done, lined with but the cheerless cement curbs and sidewalks, get but half the possible value of their expenditure. Let these street be lined with intelligently chosen, properly cared for trees, and the value of these expensive city improvements, is doubled at a slight cost.

This will prove as true of our improved country roads. For instance, if Los Angeles county would plan to spend even a very small,—an insignificantly small—fraction comparatively of the splendid sum it has voted for good roads, in their systematic, intelligent embellishment, it would add wonderfully to the real satisfaction these new road-beds will give. No other equal portion of the entire sum spent will return anything like equal value. And while the road-beds are necessarily gradually deteriorating, the broadening shade trees would be constantly improving and serve generations without renewing.

Let this policy be carried out in other countries where these expensive road-beds are now sure to be made, and it would be difficult to conceive the actual value this fraction would add, in the way of inducing appreciative people to make permanent homes in their vicinity.

Imagine the genuine satisfaction of the farmer in driving with his load of produce, in his carriage or his auto, mile after mile over shaded dustless roads, or the admiration of the visiting tourist as he enjoys his leisurely drive through the country.

Roadside Tree Planting Now.

But we need not and should not wait for the new roads now planned to commence this systematic ornamentation. This tree planting along our country highways should commence at once. Should have commenced long ago. Supposing the leading thoroughfares connecting our villages and cities, now so bare and homely, though so much traveled, had been wisely planted to shade trees twenty—ten—even five years ago, and properly cared for. Will somebody attempt to estimate the actual value as a cash asset to the counties now, say nothing of the enjoyment they would have given during all these years?

Is It Practicable?

Is successful roadside ornamentation practicable in this country? It most certainly is—as practicable as good road making. The requisites are simply a little money—little compared with value of results—judicious planning, and intelligent, systematic organized effort.

Something may be done through local improvement organiaztions. In fact much has been done in some cases, but as a rule such voluntary efforts have not proven very successful.

Heretofore the street ornamentation of our cities has depended for the most part on individual effort, with occasional help from local improvement clubs. But results have not been generally satisfactory and some cities have already adopted municipal control of street beautification, with results so satisfactory, that many other towns are planning to follow their example. There is no doubt in my mind, that in a brief time the street ornamentation of our progressive cities will be as fully and directly controlled by municipal authority as are their roadways and sidewalks.

I believe the same general principles should be applied to country roadway ornamentation, and every county have its tree warden or forester, having entire control of the beautification of its roads, with sufficient funds to gradually secure roadside tree planting and care, commencing in neighborhoods where property owners will co-operate in bearing initial expense, and after care.

I readily understand that apparently serious difficulties will at once present themselves to those who have not given the matter thought, but I am sure they can all be easily overcome when the importance of the movement is realized. The county could raise its own trees at slight cost. Necessary irrigation while the trees are young can be managed without excessive expense. The important thing would be a man with good judgment, expert in handling trees, with appreciation and love for the work.

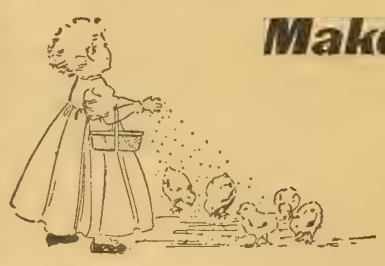
Coulson's POULTRY FOODS

Special Dry Chick Food



Makes Them Grow

COULSON'S SPECIAL DRY CHICK FOOD, during the five years it has been on the market has justly earned for itself its great reputation as a life-saver for little chicks by its special adaptation to their needs.

THE UTMOST CARE is observed in the selection of each of the dozen or more articles composing this unequalled feed; tender seeds, cracked grains blown free from dust, steel-cut oats, tiny pieces of dried meat and bone, willow and pure bone charcoal, are combined with other very necessary ingredients; every article being selected with special reference to its quality, strength, and desirability for the needs of the young chick.

FOR YOU TO BUY the many different articles composing Coulson's Special Dry Chick Food is quite impracticable; you could not be certain as to their quality for one thing, and the high cost of certain of them when purchased in small lots might lead to their being left out to the detriment of the chick.

TO MAINTAIN the high reputation of COULSON'S SPECIAL DRY CHICK FOOD, nothing is left undone to make it absolutely the best feed that can be made for the little chicks.

COULSON'S SPECIAL DRY CHICK FOOD can be fed exclusively to your little chicks for the first six weeks, at a cost of about four cents (4c) each; and what is of still greater importance, it will do all that can be done in the way of feed to bring them through that critical period of their lives in full health and vigor.

TO RAISE EVERY CHICK you hatch; to have fine, large, healthy chicks; to have chicks that will stand up and crow when eight weeks old; to raise chicks that you will be proud of, FEED COULSON'S SPECIAL DRY CHICK FOOD, THE LIFE SAVER.

DEMONSTRATION TRAIN—INSTITUTE ON WHEELS.

(Continued from Cover Page.)

Department of University Extension in Agriculture, and Southern California in charge of J. B. Neff.

The number of these institutions has increased from year to year and the farmers and fruit growers have received great benefit from them. When they are held, usually the entire day is given up to the institute, having forenoon, afternoon and evening sessions. Sometimes two or three days sessions are held.

Since the establishing of the corn trains of the middle west, attention has been attracted to the possibilities of a farmers institute held on similar trains. For two or three years some eastern states have held these institutes, always through the support of the railroad companies, who have usually financed the proposition and furnished the cars and transportation facilities. The Southern Pacific Railroad Company gave some attention to this matter nearly a year since, but until last November the way did not seem to open for such a train in this state.

At that time a train was made up and traversed the Sacramento valley. All equipment necessary was furnished by the railway company and the speakers were secured from the staff of the State University and of the State Horticultural Commission. The fourth trip of this train was announced to begin at Pasadena, Los Angeles county, Wednesday, March 10. The writer was granted the courtesy of a few days with this train and it was a most intensely interesting trip. Some facts about it and the manner of conducting the meetings may be seen in the Dairy Department of this week's paper, where Mrs. Sherman refers to her experience in the San Joaquin valley. By the way, Mrs. Sherman is accompanying this train as a lecturer on vine culture, giving especial reference to pruning the vine. On the first cover of this week's Cultivator may be seen photographs of the vines arranged in her corner of the demonstration car.

Besides the diner on which we were when Mrs. Sherman made her remark as to her appreciation of this type of institute, there was the sleeper "Khyber;" next to that the demonstration car, devoted to the exhibit made by the State Board of Horticulture. Forward of that was the lecture car which was seldom used on this trip, as the time seemed to be more satisfactorily taken up in the examination of the exhibits. Forward of the lecture car was the one containing the larger part of the exhibit made by the State University.

The first exhibit to strike one's eyes was that in charge of Dr. C. M. Haring, Veterinarian of the Experiment Station, which consisted of appliances for the sanitary handling of milk and a grewsome exhibit of tissues from diseased animals, more largely made up from those affected by tuberculosis.

On the other side of the car was an exhibit in charge of Prof. Babcock, having to do with plant pathology and containing a large number of exhibits, showing various rusts and other fungous diseases of plants. Farther on in the center of the car was the cereal exhibit of the State University, in charge of Prof. Shaw. In the next car the most attractive exhibit was that illustrating the methods of pruning and was in charge of Mrs. Sherman. Opposite that exhibit was one devoted to medical entomology, in charge of Prof. W. B. Herms. In the same car were spray pumps of the knapsack order, also of the larger hand power kinds. Another exhibit which attracted much attention was that of eucalyptus wood; axe helves, hammer handles, wagon spokes, singletrees, and other tools or parts of tools were exhibited and created much interest in the growing of this valuable timber.

A most interesting feature of this car was the display of soils in bottles which had been taken from various sections of the state. These bottles were arranged one above the other, showing the exact location from which the soil was taken. That is, if the sample was taken to a depth of ten feet, each bottle represented one foot of the soil's depth and the ten bottles showed the grading or kind of soil from top to bottom. In some of the deeper soils the character shown by the bottles was most uniform, while in others a top soil of remarkable fineness appeared, while lower either clays or gravel were shown.

These few notes do not so much as touch the great number of these exhibits especially those made in the car of the Horticultural Commission. This car was in charge of State Commissioner Jeffrey, with Messrs. Carnes, Ehrhorn and Strong assisting. As an indication of the number of insects there displayed we may mention that Mr. Ehrhorn was in charge of one exhibit of more than three hundred bottles of insects which were taken from plants and from fruits which were seeking entry at the port of San Francisco. This was a most forceful illustration of the worth of this particular arm of our state government. The white fly was there in all stages of growth and on many kinds of leaves. Another exhibit consisted of thirty quarts of lady birds in ventilated boxes, being taken to the cantaloupe fields of Imperial and Coachella valleys.

The train is in charge of Assistant General Passenger Agent T. A. Graham, with the genial Traveling Pass. Agt. F. C. Lathrop, arranging the various details of the trip. Mr. Cook of the Citrus Claims Department was also a member of the party. Immediate charge of the train was in the hands of Conductor J. M. McKinnon. Every one of these men did their best for the comfort of those accompanying the train and to make the stops at the various stations as valuable as possible to the visitors.

As an example of the courtesies extended, we might refer to the fact that at San Dimas the high schools had been dismissed to inspect the exhibits. As most of the scholars had walked some distance to the depot and as the school was near the track in the direction in which the train was going, the suggestion was made to Mr. Lathrop that it would be a great treat to the children to be carried on the train as it pulled out to the point nearest the school house, where they might be permitted to leave the train. This was promptly acceded to and the pleasure of the short ride given to the children.

When the train stopped for only an hour or two during the day time, no effort whatever was made to hold a formal meeting, but in the evening adjournment was had to the nearest

(Continued on Page 335.)

Live Stock and Dairy

Dairymen and stockmen are requested to write of their experience. Mrs. Sherman is always willing to answer queries and this, with experience of other workers, will make this department of greater value.

By Mrs. Minna E. Sherman

THE DEMONSTRATION TRAIN.

THE sun was shining on the snow of the Sierras; even the foothills were white, making more vivid the contrast with the long stretch of green barley fields. This was the picture that dazzled the eyes as I stood waiting by the roadside for the Demonstration Train, in the chill air of the early February morning. Beautiful and serene were the broad fields, but how devoid of people! The country was not covered with homes made comfortable by incomes from vines and trees. The air was not full of the joyous voices of happy children, satisfied with the simple life and not knowing of the vices that are found in a crowd.

Will the time come when women and children are in these lonely houses? The children fitted to live in the country by a knowledge of its manifold life? Children that know the trees, flowers and birds? Children growing up on the farms well instructed in the arts of making the soil yield its best harvests? Yes! the time is at hand for the Evangel train is coming! Bringing to the people the "glad tidings" of the better way of making the soil productive.

The train comes slowing to a stop, but not before several cars have glided by, covered with the colors blue and gold of the loved 'Varsity. This train carrying the gospel of better horticulture and agriculture, carries something more to the people of California, for it carries the message that a great corporation has found that it has a soul. As the train comes to a standstill, Professor Clarke's smiling face appears behind the bustling conductor. Off swings the man in uniform with a shout of "All aboard" at the lone passenger. All aboard it is in short order and away I was off for the trip up the valley. The fullness of the meaning of this Demonstration Train to the State's future prosperity slowly came to be realized as little town after little town gave their rousing welcome to the speakers.

Pie a la Mode.

Professor Clarke, as head of the University force of lecturers, was everywhere, making us all happy by kindly encouragement. It was a happy congenial family rather than a number of people out to lecture. The Southern Pacific had given its best equipment of train service, and Mr. Judah, assistant passenger agent from San Francisco, represented the railroad in the talking force, while from Fresno we had Mr. Burkhalter to take charge of the schedule on which the train ran over his division. The trip was made without a single delay or being behind at any time; this was all the more remarkable as the many "dry weather" streams were bank-full of tawny water. Even the diner was furnished with its complete force—to give well-cooked meals strictly on time. Many happy hours were spent in the diner and "pie a la mode" was a prime favorite. The standard sleeper was in charge of a porter who wore three stripes on his sleeve for long, faithful service. The train with its service was regarded as the first factor or division of the Demonstration work and Mr. Judah made the first address to the audiences telling why the Southern Pacific was deeply interested in this movement. The second part was the University with its representatives of professors and Farmers Institute workers. The third portion was the State Horticultural Commission supplemented with the workers of the Government in like matters.

The train was made up of three cars of exhibits, a lecture car, a sleeper, and the diner. The lecture car, one of the largest-sized chair cars, was used as an audience room at the smaller places. In the larger towns local committees had provided halls for the lectures. The speaking was limited in the morning and afternoon sessions to one hour and a half, while the evening sessions were longer. The speakers were kept down to fifteen minutes, then when that was up they were clicked down with a little ticker. It made the talks crisp and to the point. When the time was spent that the card allowed, Prof. Clarke would say something like this to the audience: "Now, friends, our time is up! We will adjourn to the exhibition car for we consider you are all from Missouri. We will try to 'show you' and answer your questions on the subjects we have talked about." Then came a rush to the cars, pell-mell. It was often difficult for the demonstrators to get into the car to show the exhibits.

Exhibits.

The first car carried the vine exhibit, real vines set in a bed of earth, some pruned and some unpruned, to show the proper way of handling the low pruned varieties. The trellised vines and the vertical and horizontal cordon pruning were illustrated with photographs. There were also a series of large photographs that showed bad handling. A spray pump with its various nozzles, a display of bottled sprays used in horticultural work, a sulphur machine, completed the viticulture display. The exhibition of these vines created much interest and the Italians came in bunches. At one place there was one man who acted as interpreter for the rest. The pruning of the muscat vines was their study, as they explained they did not know anything about the way to bring them into shape from the cutting. The interest in the forward part of the car centered in the eucalyptus exhibit of polished samples and in a rack of turned work in the way of handles for small tools. At one place a rusty-throated native told of the wonders and wealth to be made by planting the eucalyptus for fuel. I listened and felt a little dizzy over the amount of money I had let slip away by prosaically growing grapes; then I remembered that half mile of trees I had been glad to let out the cutting for half the cord wood, for when I cut them with ordinary labor the cost of cutting made it cheaper to buy mountain wood. I kept quiet, for I am not a knocker! I have dwelt on this

Other Cream Separators Merely Discarded or Abandoned De Laval Inventions

It is interesting and instructive to know that nearly, if not quite, every cream separator that has ever been made, and certainly all that are being made at this time are merely copies or imitations of some type of construction originally invented or developed by the De Laval Company, and either not used by it because of something more practical or else discarded and abandoned in the course of De Laval progress and utilization of later improvements.

As earlier patents have expired some of their features have one after another been taken up by different imitators, so that at all times, as is the case today, every separator made in the United States or elsewhere in the world, utilizes some type of construction originally owned and developed by the De Laval Company, though some of them have never been commercially used by the De Laval Company because of their inferiority to other types of construction used by it.

All cream separator inventions by others have been of immaterial details or variations, upon which patents have been taken, if at all, more for the sake of the name than by reason of any real value or usefulness attaching to them.

But the De Laval Company has always been forging ahead, with its many years of experience and the best of experts and mechanics the whole world affords in its employ, so that before any expiring patent might permit the use of any feature of construction by imitators the De Laval Company had already gone so much beyond that type of construction that it was then old and out-of-date in the modern De Laval machines.

The first practical continuous flow centrifugal Cream Separator was the invention of Dr. Gustaf de Laval in 1878, the American patent application being filed July 31, 1879, and issuing as Letters Patent No. 247,804, October 4, 1881.

This was the original Cream Separator—of the "Hollow" or empty bowl type—and it has been followed from year to year by the various steps of cream separator improvement and development, all De Laval made or owned inventions, the American patent applications being filed and letters patent issued as follows:

The original hand Cream Separator of the "Bevel Gear" type; application filed October 2, 1886, issuing as Letters Patent No. 356,990 February 1, 1887.

The original hand Cream Separator of the "Spur Gear" type; application filed January 17, 1887, issuing as Letters Patents No. 368,328 August 16, 1887.

The original Steam Turbine-driven Cream Separator; application filed December 8, 1886, issuing as Letters Patent No. 379,690 March 20, 1888.

The original "Tubular" shaped "hollow" bowl Cream Separator; application filed April 19, 1886, issuing as Letters Patent No. 372,788 November 8, 1887.

The original "Disc" bowl Cream Separator; application filed May 12, 1890, issuing as Letters Patent No. 432,719 July 22, 1890.

The original vertical "Blade" Cream Separator bowl, covered likewise by the application filed May 12, 1890, issuing as Letters Patent No. 432,719 July 22, 1890.

The original "Bottom Feed" Cream Separator bowl; application filed July 24, 1889, issuing as Letters Patent No. 445,066 January 20, 1891.

The original series of "Star" or "Pineapple Cone" shaped cylinders Cream Separator bowl; application filed August 24, 1893, issuing as Letters Patent No. 521,722 June 19, 1894.

The original "Curved" or "Converging Disc" type of Cream Separator bowl; application filed January 18, 1905, issuing as Letters Patent No. 892,999 July 14, 1908.

The original "Split-Wing" Tubular Shaft Cream Separator bowl; application filed April 29, 1898, issuing as Letters Patent No. 640,358 January 2, 1900—which invention, with a number of later improvements, is the type of bowl construction used in the De Laval machines of today, still covered by protecting patents which prevent its appropriation by would-be competitors.

The patents thus enumerated are but a few of the more important of the more than 500 original Cream Separator patents owned, controlled and developed by the De Laval Company during its thirty years of creation and development of the Cream Separator industry throughout the world. They are recited because they show in the most illustrative and conclusive manner possible De Laval originality and leadership from 1878 to the present day.

In addition to these patent-protected features, the De Laval machines have within two years been mechanically re-designed and re-constructed in every part, from top to bottom, so that the new 1908-1909 line of De Laval machines are today, even more than at any past period, fully ten years in advance of any other cream separator made.

These are the Rock-of-Gibraltar-like facts against which the mere "word claims" of would-be competitors fade away like the mists of night before the rays of the morning sun.

car as I was in it and consequently knew more about the people's opinion of the exhibit.

Bugs.

The next car was the exhibit of bugs and insects, scales and blights, and remedies for the same, with Professor Clarke in charge; also an exhibition of sulphurs. Mr. Symmes had the dairy division; overhead were placards on pertinent questions about the cow, about the uses of the Babcock test, and sample cards of the different forms for keeping milk and butter records of individual cows. Then came the ghastly display of jars of preserved meats from diseased animals. The manikins of horse legs, showing side bones, splints and spavins, while the head of a double-headed calf had always a ring of "kiddies" open-eyed around it. Dr. Shaw had an interesting lot of cereals with regional varieties of alfalfa, and also new fodder plants now being introduced. The greatly increased yield by proper cultivation and by selection of varieties is almost too wonderful to be told. Wheat, barley, rye and oats are all showing that pedigreeing or breeding up will make them as productive as it has made the dairy cow. Next came the lecture car, and following it the exhibition car of the State Horticultural Commissioner, in charge of Mr. Ehrhorn, second Horticultural Officer of the State and Chief of the Quarantine at the port of San Francisco; also Mr. Carnes, in charge of the Insectary at Sacramento, where the predaceous insects from all over the world are gathered together and bred in quarantine to send out to the fruit grower to hold the fruit pests in check. Mr. Maskew also was there, who proved to the people of the State in the campaign against the white fly at Marysville that his ability, as shown when a local horticultural commissioner of Los Angeles, had not been over-rated. Peach yellows and scales were among Mr. Maskew's many topics.

300 Bottles.

Overhead on a rack was the long line of three hundred bottles, each containing a pest that had been found on plants or fruit at the port of San Francisco and kept out of the State by the vigilance of the Horticultural Commissioner. The most dreaded at present is the maggot found in the oranges in parts of Mexico; anyone bringing a few oranges into the country in a hand satchel may bring this pest. The small plants that people carry from the Orient, as well as the wreaths and palms on the coffins are all confiscated and burned. Nothing seems to escape the vigilance of the horticultural officers.

Mr. Carnes had the lady birds and also a case of insects from other parts of the world, showing the mimicry of plants in their forms and coloring. The school children were interested in these, showing that the picturesque side of nature study was familiar to them. In this car—I will not mention where—was a case of hugging and kissing bugs that was greeted often with giggles and blushes by the high school misses. "One isn't any good without the t'other," said one girl, appealing to the man in charge. After looking around to see who heard it, he assured her that she was correct from a nature study point of view.

When writing Advertisers, mention Cultivator

hours had passed, the train was ready to move. "Toot, toot" came from the engine, and the conductor, in his brass buttons, began to head the people out of the cars, locking the doors behind him. From the head car I moved down with the people and watched them filing out of the cars. They went reluctantly with many a backward glance, and the remark was frequently heard that the stay was too short and they hoped we would stay longer next time.

At night, when the talks had been made and the train was resting on a quiet side track until morning, we would gather into a family group and chat over the events of the day, tell a few stories and one by one drop away into the comfortable berths, thankful for the hospitality of the Southern Pacific Company. At times all were tired, yet the thought was cheering that there was a better and fuller life for the people on the farm easily within reach of all. We all believe this fully, and gladly give our strength to helping forward that happy day. Not to believe this is to doubt that God knew what was best for man, for it was He that made Adam a farmer.—M. E. Sherman.

HORSE MANAGEMENT.

A sudden change of food in horses is always dangerous, but to start a colt in on grain, with heavy work, that has never had either, is almost sure to be disastrous, writes G. H. Glover, D. V. S., Colorado Agricultural College. A young horse especially cannot stand heavy pulling all day on soft ground unless his shoulders are well hardened by regular work in the collar.

Here are a few suggestions which will be well worth remembering: When a horse is tired, he is much more subject to colic. Do not change the feed on the horse during heavy spring work. There is much more danger in feeding corn or wheat than there is in feeding oats. Water your horses when you first bring them in from the field; then let them eat hay for a half hour, and give them their grain last. Pull their shoes off while doing the spring work.

Remember, the horse will have a heavy coat of hair and will, therefore, sweat easily and be all the more likely to catch cold and get pneumonia. For the first week or two bathe the neck and shoulders with cold water every night after the day's work is done. See that the collar fits snug and that the hames are buckled up tight. The shoulders are less likely to be scalded and bruised without a pad than with it. If the horse gets sweenied, he will have to be laid off for several months. Guard against that dangerous disease—azoturia. This disease almost invariably comes on after the horse has been resting two or three days during a storm and kept on full feed. Reduce the grain at least one-half while the horse is not at work.

Founder is caused from too much feed, a sudden change of food, or a drink of water when the animal is warm. Distemper is especially liable to attack the young horses in the spring of the year, just when their services are most valuable. This disease is contagious, and care should be exercised against exposing the young horses to the infection. The most common way that young horses get this disease is when they are taken to town and allowed to drink out of public watering troughs and tied to hitching posts where other horses have been tied that had the disease.

AMERICAN FENCE

To get the most out of a farm, every square foot must be either tilled or else made to produce feed for live stock. A fence all around the farm, then cross fences, making more and smaller fields—permitting rotation of crops and change of pasture—are first essentials in making possible maximum earnings.

Here are two great fences—the best square mesh and the best diamond mesh. We selected these two styles years ago, after careful study and advice from many of the most experienced and successful farmers, the correctness of which has been verified by actual results in the field. These fences are the simplest in construction; are made of any size or weight of wire desired and perfectly adapted to all uses and conditions.

If you want square mesh, buy American; if you like diamond, buy Ellwood. You can safely take the verdict of the millions of farmers who have tested and tried out these two great fences. Dealers everywhere, carrying styles adapted to every purpose. See them. Catalogue for the asking.

DEMONSTRATION TRAIN.

The Fourth Farmers' Institute or Demonstration Train is near the end of its fourth trip in this State. One of the first efforts along this line by the railroad people was that of the railroads of Iowa and the middle west in their "corn trains." These corn trains proved such an inspiration to the farmers along the lines traversed by them that a new uplift was given to the calling of agriculture, especially corn growing. The Iowa farms became vastly more productive. The movement spread and other railway companies have taken up similar movements.

The first one in California was last November, when the northern part of the Sacramento valley was visited by a train furnished by the Southern Pacific Railway Co., and equipped with exhibits by the College of Agriculture of the University of California and the State Horticultural Commission.

A few weeks later a second train made a trip through the southern Sacramento valley and the northern San Joaquin valley; a few weeks ago a third toured the southern San Joaquin valley, and last week a fourth trip was started from Pasadena and is now in the Imperial valley showing the "low down" farmers the work done by the Horticultural Commission and the Agricultural College for California farmers.

Incidentally there is being distributed to the cantaloupe growers of that section at the same time, about 30 quarts of the common California lady bird, which will prey upon the melon aphis. Particulars of this work may be seen in the editorial notes made during the few days' trip of this train.

In this place we wish to simply call your attention to the great work being done by these allied interests. All should have large credit for joining in this work which can only lead to greater profit to our farmers, which means greater prosperity to the State.

With it all, however, it is strange to note that the farmers and others, while justly granting credit to the University and Commission for their part in the movement, promiscuously condemn the Southern Pacific Company on general principles. We say it is strange, for while it must be recognized that strong prejudices often warp one's judgment, they should not blind one to see the good which is being accomplished. If work is done which is worth being condemned, let the condemnation be visited; on the other hand, when real worth and public-spirited effort is made, the commendation should be as emphatic as was the condemnation.

It is true that this work is taken up by the Southern Pacific Railway people because of selfishness, but it is such an enlightened selfishness and means so much for the advancement of the State that all may praise the public-spiritedness of the big corporation.

We say it is from an enlightened selfishness for, as Assistant General Passenger Agent T. A. Graham remarked to us: "If we can induce the farmers to destroy the bugs and diseases that are continually reducing their output, our tonnage will be increased to that extent." The railroad people realize that until the farmer prospers the railroads will not prosper. Nevertheless, give them due credit for this effort leading towards greater prosperity to the farmer if he will but come to these trains and ask for information.

SCHOLARSHIPS AT STATE FAIR.

The Iowa State Fair Association is offering prizes in judging contests at its next fall state fair. A series of scholorships for boys and girls of that state will have a most practical value to the youngsters and will, we believe, prove a drawing card for the fair. That such a contest must be of inestimable value will be seen at a glance, and the result will not be so observable this year as it probably will in years to come when Iowa agriculture will benefit by the uplift given to these young people entering into a contest which must necessarily spur to greatest effort and to most earnest study of principles which underlie success.

The girls' contests have to do principally with baking and cooking and recipes for doing the work. Each contestant must mix and bake one dozen baking powder biscuits and must cook one beefsteak. Each must also give in writing the recipe she used, method and time of baking and the reasons for the method used. She must also give in writing recipe for cooking beefsteak and reasons for her method of cooking. The contestants will be allowed one hour and fifty minutes for doing the work and writing recipes. The scale of judging is for finished products 40 points, method of working including accuracy and quickness 20 points, reasons for method 40 points. The scholarships are worth $150, $100, $75 and $25 each.

The boys' contest is open to any boy under twenty-one years of age who has never been classified in any college. The contestants will be required to judge two rings each of horses, cattle and swine, consisting of three or more each, also two or more varieties of corn of ten ears each. The contestants will be allowed twenty-five minutes to present and write reasons, substantiating their judgment on corn and each class of animals. Every contestant must also bring one ear of corn which will be passed upon by an expert and to each contestant bringing the three ears, placed first, second and third, will be given additional points of merit to their total score. The boys' prizes are scholarships of a value of $250, $150, $125, $100 and $25. The money is to be deposited with the treasurer of the Iowa State College of Agriculture with the instructions that the money is to be paid to the boys winning the contest at the rate of not to exceed $25 a month.

In addition there is a special $50 prize to the person or association which secures the entry of the greatest number of contestants.

SUPPORT THE DAIRY INDUSTRY.

A bill has been introduced in both houses of our state legislature, which calls for an appropriation of $25,000 a year to carry out the law in regard to the sanitary conditions of dairies and cheese factories with regard to dairy products. We have heard no objections to this bill and it certainly aims at great benefit to the industry, which needs encouragement in this state. We are now importing hundreds of car loads of dairy products and with our rich alfalfa land and with every facility for manufacture of highest grade products, we should keep more of this money with our own producers. If a system of inspection will aim to raise the grade of our butter so that it will command better prices and in turn yield to the manufacturers and producers more net money, we believe the greatest step will be taken toward meeting the demands of our people.

Another bill contemplates the branding of cold storage eggs in a way that every buyer may know what he is purchasing. This is another excellent bill, for the way in which cold storage eggs have been used to bear the market discourages home industry and is worthy of condemnation and more worthy of being forced into the open. Those who handle that class of goods must sell them for what they really are. The producers of this state have vastly more to do with the health and prosperity of this state than do the speculators in food productions.

SELF SUPPORTING INDIANS.

Mr. G. P. Rixford, special agent of the Department of Agriculture, writes the Cultivator that efforts are now being made at the Colorado Indian Reservation in Arizona with Egyptian cotton with the hope that the result may lead to the production of a crop which may be taken up by the Indians of that reservation, also by those of the Fort Mojave reservation, and by them made an industry by which they may be self supporting. Mr. Rixford writes: "The Commissioner of Indian Affairs of the Department of Agriculture is co-operating in this work as the experiments promise to afford the Indians a means of making money by growing this valuable staple. Last year the price was 25 cents per pound and the United States imported it to a value of $16,000,000. The arid region of southeastern California and southern Arizona will have a monopoly of this crop as it will not grow in the moist atmosphere of the southern states."

The experiments have been very successful in the Imperial valley and the quality has been pronounced superior even to the imported fibre. It is now a question only of labor but at the high price of this long fibre it is entirely probable that the labor question will be settled. In any case, this effort to encourage the Indians in its culture is very gratifying.

COW TESTING.

The Humboldt County dairymen are taking a long step in advance in their organization of a "Cow Testing Association" through which they hope to weed out the deadhead "boarders" from their herds. One small association conducted this work through part of last season and found many cases which were drones and being supported by others of the herd. These have long since gone to the block and the dairying been conducted on a more profitable basis. The work of the Humboldt dairymen should be an incentive to every other section of the country to take a similar step.

A Coachella subscriber writes the Cultivator asking as to the advisability of a personal canvass being made to secure reform in our postal service which will be beneficial to the farmers. Above all he would urge that every farmer in the country would express to his member of Congress the fact that he wants "parcels post." If such a campaign could be set in motion it would doubtless lead to results but the difficulty is to awaken the farmer to his own needs sufficiently to get him to write such letters.

Agricultural Notes of the Pacific Coast

Northern California

Colusa county is talking up a special bond election for good roads.

Colusa has the banner sheep shearer of the state who claims to have done 135 sheep in one day.

Farmers in Guinda, Yolo county, report more damage from coyotes this season than for some time.

San Francisco Produce Exchange has ruled out "pullet eggs" as a separate class and they will hereafter go as "thirds."

One hop grower at Ukiah has sold his hops for the next three years for 10, 10½ and 11 cents per pound for the whole crop.

Mountain lions near Grass Valley, driven down by the heavy snows in the mountains, have killed many calves and sheep.

Ritchey, Amador county, reports the coming apricot crop as almost a failure, peaches a half crop, and prunes showing up well.

The Messrs. Miller & Sons report almonds at Ritchey, Amador county, promise a fine crop though the bloom is fully two weeks early then usual.

A movement is on foot in the Sacramento valley to get the people to combine to fight the dredger miners and prevent filling the rivers with debris.

A Colusa county farmer has forwarded to the Plant Introduction Garden at Chico sample roots of a native wire grass which it is thought may develop into a splendid matting grass.

The Winters Canning Company at its recent annual meeting received a report from its manager showing the last year to have been an exceptionally heavy one.

An effort is being made to secure the straightening and improving of the drainage of Cache creek from Clear Lake, Lake county, so as to make better disposal of storm water.

A wool buyer of San Francisco, recently returned from a trip over the East, reports that a good condition of the market prevails and that the feeling exists that tariff revision will not affect the wool industry.

The annual meeting of the Sonoma County Horticultural Ass'n. recently elected A. R. Galloway president, and W. I. Newcomb secretary. The association has asked the county supervisors to employ an expert entomologist.

The engineer in charge of the Orland irrigation project announces that work will soon be started in planting various fruits and other crops. As an experimental proposition amongst other plants will be the long-fibred Egyptian copper.

Sutter county will beat all previous records in acreage of fruit trees planted this year. It is estimated that at least 1200 acres of trees will be set. Of these 500 will be in grapes and 400 in Tuscan cling peaches. An important fact is that there will be about 150 acres of apples planted.

Sheep men of California won an important victory through the efforts of a sheepman of Red Bluff. He had been arrested for violating an ordinance imposing a license tax of five cents per head on sheep raising in that county. The appellate court held that the license was unreasonable.

Central California

A section of land will be planted to eucalyptus near Alpaugh, Tulare county.

Hanford has a single branch of osage orange which grew 20 feet and 9 inches in one season.

The Farmers Union is endeavoring to work in line with the trade unions of the country in the disposal of large quantities of raisins.

Consumers are complaining of the higher prices of beef, though the producer, while he gets but a small part of it, is more pleased.

Six hundred farmers were present at a Farmers Union in Kingsburg recently and it was decided to locate headquarters at Fresno.

Dairymen of Santa Rita are making more cheese than butter as the cheese factories have proven more profitable during the past few years.

Sequoia Park is to have a better accommodation for soldiers quartered there, which will consist of four sets of officers' quarters and one set of barracks.

A horticultural society has been organized at Hanford, the object of which will be primarily the improvement and beautifying of roadsides and parks.

The raising of oats has proven profitable to some farmers near San Miguel, San Luis Obispo county, and large acreage has been planted the past season.

Hanford has a small experimental forestry farm on which a large variety of eucalyptus trees have been planted and are all showing exceptional growth.

The Pacific Sugar Company, which has factories at Visalia and Corcoran, has levied an assessment of $3.00 and $17.00 per share to aid in preparing for the coming season's run.

The Fresno raisin people are talking of inaugurating a campaign of advertising raisins in the East similar to that carried on by the citrus men of the southern end of the state.

At a recent meeting of the Central California Health Officers' Association, the question of California sulphured fruits and effects upon the system, was discussed by A. J. Watkins of San Francisco.

Agents of the Department of Agriculture are giving information to the orange and lemon shippers in the Lindsay and Lemon Cove regions, as to the best methods of picking and packing fruit.

One steamer recently cleared from San Francisco with 2,579,838 pounds of dried fruit, mostly prunes. This gives the fruit growers of the prune section reassurance as to light hold-over crop, especially if such shipments continue.

The Saratoga Blossom Festival is being celebrated amongst prune blossoms this week in that beautiful suburb of San Jose. The railroads are offering special inducements and vast numbers of visitors, from San Francisco especially, are expected to be poured into the prune orchards to revel amongst the blossoms.

Later: A letter informs us that Blossom week will be from March 20-27 and Blossom Day March 27.

Southern California

Cabbage is now going out of the Fullerton district in carload lots.

J. B. Neff of Anaheim has a force of men grafting over several hundred walnut trees.

The city trustees of Redlands have accepted plans for extensive roadside ornamentation.

The Farmers Institute train is making its first visit to Southern California this week.

Sandhill cranes are doing great damage to grain in the west end of Antelope valley.

Arlington Heights Fruit Company recently forwarded a car of oranges to London, England.

The Coachella valley claims it will have cantaloupes at least a month earlier than last year.

Smeltzer, Orange county, is shipping largely of Globe artichokes to the Los Angeles market.

Orange county celery campaign is practically closed and shows a shipment of about 1500 carloads.

One farmer at Thermal, Riverside county, is sinking a well 1000 feet deep, for an irrigation supply.

The work is going ahead rapidly on the survey of the canal from the Colorado river to Coachella valley.

After many troubles with the veterinarian of Orange county, the Board of Supervisors have voted to discontinue that office.

The number of poultry in Southern California is said to have greatly decreased during the past year, owing to the high prices of feed.

Coachella cabbage growers are pleased with returns being received for this season's output; $40 and upwards per ton has been netted.

The Cawston Ostrich Farm at South Pasadena is transferring its largest producing farm from Orange county, to Perris, Riverside county.

The beet fields about Santa Ana, of which about 4,000 acres are planted, are making an excellent showing. The company supplied the farmers with over 100,000 pounds of seed for this year.

Notwithstanding slightly reduced prices for oranges many orange groves in the vicinity of Riverside have been sold recently. One real estate company reports the sale of orange property aggregating $100,000.

An Antelope valley orchardist has an eight year old apple tree which gave to him last year 1200 pounds of apples. If he had an acre, each bearing as well as this tree, it is estimated it would net him $3816 per acre.

At a recent meeting of the directors of the Santa Ana Valley Walnut Grower's Association, A. C. Tiede was elected secretary. Association shipped one million, five hundred thousand pounds of nuts during the season, which brought the growers 10½ cents.

Prof. Ralph E. Smith of Whittier is the subject of a two page article in a recent Saturday Evening Post. The discoveries which Prof. Smith has made in his lemon rot investigations which have been of such great benefit to the citrus interests are particularly referred to.

The Coast

With wheat at $1.20 and going up Inland Empire farmers are highly elated.

Portland reports that horses are higher in price and scarcer than for years.

A large colony of people from Iowa has been established at Wenatchee, Wash.

The Portland horse and cattle sale will be held this year from April 26 to May 1.

One planter near Portland, Ore., will make a setting of 225 acres of walnuts this spring.

The largest dairy ranch west of the Rocky Mountains is said to be located at Rosalia, Wash.

Oregon hops are looking better and it is hoped the 10 cent price will soon be reached at Portland.

The highest temperature at Phoenix, Ariz., during February, was 77 and the lowest 32 degrees.

Farmers at Juliaetta, Idaho, are engaging more and more in the culture of beans and corn as staples.

Ranchers in the Yuma Valley, Arizona, are planning to plant large crops of barley this spring.

Ranchers near Ephrata, Wash., are having success with the irrigation of large orchard tracts from wells.

Many beneficial birds have been slaughtered near Rosalia, Wash., by poison placed for ground squirrels.

Feed barley is selling at $1.75 per hundred at Grangerville, Idaho, the highest point ever known at that section.

Fall sown wheat at Palouse, Washington, as fast as uncovered by the melting snows shows an excellent condition.

Washington's birthday was celebrated in Portland, Oregon, by young ladies planting rose bushes along the streets and in the parks.

Engineers of the Great Northern Railway have completed a survey in eastern Washington which will open up much new fruit country.

University of Idaho Demonstration Train has been granted a large audience at every point, and is giving general satisfaction to the farmers.

State Board of Horticulture of Washington is concerned over the appearance of brown-tail moth which has appeared in sections of Marion county.

The Yuma County, Arizona, Commercial Club has forwarded a memorial to Congress asking for the dredging of the Colorado river from Yuma to the Gulf.

The big Laguna Dam a few miles above Yuma across the Colorado river is almost a mile long. The entire dam will be finished, it is now estimated, by April first.

A so-called "rainmaker" at Moro, Ore., has more nerve than our common California one, for in this case he wished $15,000 to carry on the season's work in one county.

The first fruit growers' demonstration train to be operated over the line of the Northern Pacific in Washington ran last week, starting from Kennewick and ending at Ellensburg.

Profit in the Poultry Yard

By Mrs. Frank Metcalf

We solicit short articles of a practical nature from the fancier and utility breeder, giving their experience with poultry. All inquiries pertaining to feed, management, disease and its prevention will be answered through these columns.

METHOD OF POULTRY RAISING.

(A continuation of last week's article)

THE question of how best to hatch our chicks comes next; the farmer's wife has little time to raise chicks, and must consider whether she will use incubators or hatch with hens. I am old-fashioned and like hen-hatched chicks, and believe they make the best layers and longest lived birds.

I know Biddy is tricky and notional when it comes time to sit. I know her failings well after many years' trials with her, but I also have had trouble with incubators, yet incubators have their place.

It is pretty discouraging to have a hen leave her nest, but it's a heap more provoking to run a machine three weeks and have a few miserable little cripples for your trouble, too.

A good hatch where a fair percent of fluffy little babies come to the glass doors to greet you, is a sight to repay you for all your bother for the time being, but a few weeks later, somehow your interest begins to wane, and they are neglected a little too long some fine evening, and you will find them bunched, and a dozen or two dead. Or the lamp may explode and burn chicks, building and all. I nearly lost my life in trying to save 75 fine early chicks in one such fire, but my boy came to the rescue and saved me with the loss of his eyebrows and a very badly burned hand, but saved very few of the poor little chicks. But incubators we must use if we raise many market chickens, for the incubator will work when the hen will not. There are many good makes to be had, and any one can succeed who will simply follow directions.

Brooders.

Fireless brooders are the kind to use in this country, and are on the market, but a jug of hot water in a well packed hay box on the plan of a fireless cooker, will bring a lot of little chicks through a cold spell very comfortably. A brooder house should be large enough for one to go inside to work in. I used to have little buildings six feet square, made of old boards, with tight board floors, and covered with tarred paper, in my old Ohio home.

I had a shelf of boards two feet wide across one end, with a curtain in front and a safety brooder stove underneath, with drum and pipes for heating, but would now simply use a hay box in cold weather, filling the hot water jug twice in each twenty-four hours. In such a building I have raised 100 chicks nicely, marketing the surplus cockerels very early, allowing the pullets more room. One window and one door should be put into these houses, with extra windows of screen wire for warm nights; canvas or glass for cold weather. In summer this building should have a shady place, or the chicks will overheat, which is fatal.

Food.

Start chicks on the prepared chick food, but as they grow older mix your own food and feed liberally, but not wastefully. A good mash mixture is: bran 25 pounds, cornmeal 25 pounds, middlings 25 pounds, alfalfa meal 8 pounds, bone meal for chicks 10 pounds, meat meal 10 pounds. Mix with milk whenever possible, or feed dry, or mixed to a crumble mass with water. The dry stuff should be dumped upon a floor and shoveled over several times to thoroughly mix it, then kept in boxes or bins. This is also a good egg ration.

Green feed must be provided for, and a good way is to sprout barley, wheat or oats. It is prepared by soaking the grain over night in a tub of water, then spread about three inches deep in boxes that will leak, and cover with bags. Sprinkle well twice a day, and stir once a day to keep it from burning. In about a week it will form a mass of green sprouts and white roots which are greedily eaten by old or young fowls, furnishing them with fresh succulent feed at very moderate cost.

A slatted run in which to put the chick food where the older birds cannot get it, is a necessity on the farm for the chicks must be kept growing and a trough of cracked corn and wheat should be kept where they can run to it at all times, besides the mash food. I like gallon milk crocks for drinking vessels, as they are easily kept clean and don't upset readily; a piece of board should be put in each one so chicks will not drown, an old round churn lid being a fine contrivance.

Mites.

I use gallons of distillate since I have learned how it destroys mites. I drench the nest boxes, and the coops in which chicks are kept with hens, the brooders and houses, spraying it freely into all cracks and crevices where these vermin hide.

Mites breed in dark and hidden places like bedbugs, and come out at night to annoy the birds, but are invisible daytimes like their disreputable cousins. Anything to destroy them must be used freely, to penetrate their dark abodes. Boiling water will do this but it takes so much and cools so rapidly that it is unreliable. Once get a building thoroughly soaked with kerosene or distillate and mites stay away. Body lice are the worst enemy we have to deal with, and I believe more chicks are lost by head lice than any other cause, when hatched with hens. All during the time the hen is sitting, she should be kept dusted with sulphur, which is cheaper and more effectual than Persian insect powder, which is not always fresh. When the chicks are taken from the nest, take fresh lard and grease them well on top of the head and around the neck, under the wings and between the thighs, treating the hen in the same way. Nearly always from one to a dozen head lice will be found on each chick, which would soon sap the life blood and cause the fatal sleepy sickness we hear so much about.—Mrs. Frank Metcalf.

120 ACRES OF FOWLS

Nearly everybody interested in poultry knows U. R. Fishel's 120-acre Poultry Farm at Hope, Ind., where he breeds thousands of White Plymouth Rocks—more than any other man in the world. Mr. Fishel's great experience makes his opinion most valuable to poultry raisers. He writes us as follows: "*After using Incubators for nearly 25 years* I must say that your latest pattern machine is the most complete hatcher I have ever tried. Last year we reared more chicks than ever before, and they came out stronger and grew faster. I am mailing **PHOTOGRAPH OF THE COCK "Prince of Indiana" which I SOLD FOR $800.00**

He was Hatched and Reared in Cyphers Machines

Mr. Fishel also writes us about our New Fire-Proofed Insurable Incubators. This is what he says: "*Your fire-proof improvement I consider has saved me an expenditure of something like $500 for an incubator house.*" HE KNOWS! He knows that by using our New 1909 Pattern Incubator he not only gets the World's Best Hatcher but can get insurance without building a special incubator house to hold it. He can use it in his residence if he wants to.

Don't you also want to know all about this Superior Incubator—the one he uses—the one that has helped make him the leading breeder of America in White Rocks? If you do, just write for our Big Illustrated Catalogue of 212 pages, containing chapters on poultry raising. If you mention this paper when writing, we will send it to you Free of Cost—postage paid. Address nearest office.

Breaking Up the Sitter..

Will you please tell me the best way to break up a sitting hen. Also why cannot my chicks (set under a hen) get out of the shell? And what shall I do to help them out? Shall I crack the shell?—F. D., San Gabriel.

I find the kindest and best way to break up a sitting hen, is to shut her in a coop by herself, or with others of like disposition, in which there is no nest, nor material for making one. Some use coops with slatted floors with good results, but I like better a small yard to shut them outdoors daytimes with some loose ground to scratch in. Feed and water them well for a few days and return to the yard, and usually they will not go back to the nest, but in some cases a second or even a third confinement will break them of their yearning for a family. This yearning is natural, and should not be met with harsh treatment, but only the kindest methods used to thwart the mother instinct which God has implanted.

The best way to help little chicks out of the shell, is to take a sharp-pointed pair of scissors, and very carefully open the air chamber end of the shell and if the chick has broken the skin, it will usually be strong enough to get out itself, but if the skin is not broken a very delicate touch is necessary to open that, and after the chick gets air, it can usually break the shell unless extremely tough, in which case crushing it ever so carefully in the hand will loosen the membranes surrounding the chick so one can peel the shell quite off the little prisoner, and often save its life. Sprinkling the eggs a day or two before hatching time often helps the chicks, using warm water.—Mrs. F. M.

CHAT.

I am a subscriber of the Cultivator, and being a full-fledged chicken crank on anything in that line, I must say the Cultivator is a very interesting paper for us all.

Now about poultry raising for profit. I would like to hear from those who are receiving a profit and all about how much it has cost for feed and the results from the number of fowls fed, and the length of time. Give us the figures and explain briefly. Don't fail to tell what variety of fowls you have. I tell you it will not be overlooked by any of us who are trying to raise poultry for profit.

I fed 27 head of birds through the month of January, 14 of them laying hens. I received 26 dozen eggs. I deliver to my town people, private families, and receive the same price as merchants do. My eggs brought me $9.75. I paid just $3 for feed and my hens had a free range on green feed. My birds are a fine strain of Black Minorcas.

I feed a bran mash in the morning, early, and a handful or two of beef scraps in it. At night I feed Kaffir corn one time and wheat the next. I never have sick birds. Some one is always saying, keep your hen house clean and keep this and that here and there, and so much shade and so much sun, and have your house so and so, and be sure to keep grit and fresh water by them. Well, yes, we sure look after the details all right.

I could write you a lecture a mile long on poultry raising, for I have been in the work for a good many years. But now let us give results and figures. That is what will help us altogether. Then you will see some chick chat that will cause us all to sit up and take notice.—D. W., Rialto.

Special Prices

Today we have on hand a few of the latest models of the "Old Trusty" Incubator, just as long as they last you can have them at the lowest prices ever made by any Incubator company in the West. We wish to get our money out of them quickly, we will hold any machine you wish to select if you send a $2 deposit, these machines will not last but a few days at these prices. Now is the time to BUY and save many dollars while you can. This ad may not appear again. If you do not have the catalogue, 148 pages, send for it. We pay R. R. freight in Cal. 120 Egg Size, $10.90, 165 Egg Size $12.90, 240 Egg Size $15.90. These machines are all complete with all attachments ready to run.

E. E. McClanahan

112 E. Eighth St., Los Angeles, Cal.

When the chicks are hatched don't feed them anything for 24 hours, then feed them the best dry Chick Feed you can get. We say that is

West Coast Chick Feed

Read what others say:

SAMUEL R. KELLAM, former president of the L. A. Co. Poultry Association, says: "West Coast Chick Feed is the best feed for young chicks I have ever used. I have given this feed a thorough test, and have always found that it produced fine, large, healthy chicks."

MRS. A. BASLEY, the celebrated poultry authority, says. "I want some more of your West Coast Chick Feed, for it is excellent. It is purer, cleaner and appears better balanced than other feed I had been using, and to tell the truth, I have been experimenting, feeding both together, and they always eat yours in preference."

Ask your neighbors, for there is more of "West Coast" sold in Southern California than all other kinds put together. If not sold by your dealer send us $3.50 and we will send a 100 lb. sack, freight prepaid within 300 miles.

The Model Poultry Farm
Box H, Irvington, Cal.

CARE OF THE CHICKS.

Given vigorous parentage, a caretaker who has a fair share of brains and common sense, and some knowledge of, and love for, the poultry business, there should certainly be a far larger per cent of the number of chicks raised that are hatched than is usually the case. While there must be some variation of the methods employed in rearing chicks by use of brooders from that used where chicks are raised with hens, the main conditions must be the same, including warmth, cleanliness, freedom from vermin, proper food and drink, and plenty of exercise.

For first 24 to 36 hours after hatching we allow chicks to remain quietly under the hen or in brooder, only satisfying ourselves that they are warm and comfortable. We follow the method of dry feeding almost entirely, as the mortality from bowel trouble is much less. For the first few days we feed only dry bread crumbs and pin-head oatmeal, giving water or fresh sweet milk to drink, in vessels that exclude both dirt and bodies of little chicks, as to get thoroughly wet while so young is almost sure death to them. We also scatter sand on the feeding boards and keep a dish of finely ground oyster shell and charcoal where they have access to it all the time.

After chicks are a week old, we feed millet seed, cracked wheat, dry bran, buckwheat and some of the prepared chick foods, also a little chopped lettuce or onion tops, or any vegetable that they seem to relish. The millet and other whole grain is to be thrown in litter to be scratched for if too early to give chicks free range.

At about the third week we begin to feed a little cooked lean meat and ground bone. This must be fed very sparingly at first, and the quantity fed increased as it seems to suit them. After chicks are a month old I feed grain in variety, wheat, oats, corn, etc., and keep up the milk for drink. Then if you provide a dry comfortable place for them to roost and to take shelter from storms, you may relax your care and allow them to hustle for themselves the greater part of the time.

To lessen labor in feeding, I place the coops containing the chicks in a circle and in the center place a light slatted coop covered with wire netting, and throw the feed for chicks in that. This is economical as well as time saving, as the hens are debarred from helping themselves from feed intended only for the growing chicks. The hens which I keep confined in coops all the time can be fed morning and evening while the chicks are eating.

In using a brooder, the chicks must be carefully watched to see that they are comfortable. Some brooders are so defective in construction that it is almost impossible to keep a proper temperature at all times, then after chicks have been well chilled or almost baked, the most dreaded ailment, bowel trouble, appears. The feed is changed to remedy this condition, but before the cause is located a great many poor "baby biddies" have "turned up their toes." With a proper regulation of heat, dry food plenty of grit and fresh water or milk to drink, the chicks are contented and thrifty, and do not have lice to contend with as do those reared with hens. However, if the hen is well dusted with good insect powder two or three times while sitting, she will be reasonably free from lice, and by going over the chicks once a week for a short time the lice will have to look for other quarters.

Little chicks should be fed often—perhaps half a dozen times a day—not too often the first two weeks, gradually decreasing number of feeds a day until at five weeks three times a day is sufficient. To feed a little at one time, but often, is a good rule for young chicks, as their digestive organs are easily overtaxed.—Commercial Poultry.

POINTERS ABOUT ROOSTS.

Have the roosts on a level. If some are higher than others, the top roost will be overcrowded, inducing restlessness and quarreling, while the lower roosts will be almost empty. A smooth, stout board, three inches wide, is the size I prefer, though small poles of sassafras are not pleasant to mites. If poles are used, I would advise getting large ones. Hens do not need to twine their toes around the roost in a house, as they do when roosting in trees.

The roosts should be strong and free of slivers for two reasons; the slivers often cause sores on the chick's feet, and are such fine harbors for mites. But for ease in removing and cleansing they should be light in weight. Through the winter the fowls remain several hours on the roost so it is best to have them as comfortable as possible. It is much easier to have smooth, strong roosts of the proper height than it is to fight mites, or to doctor injured feet, so from a selfish view it is best to use some care and time in fixing them.

Any lightweight hen wants to roost high, and can do so without injury to herself, so if your flock is lightweight, have the roosts on the high order. This will satisfy the hen, and will result in no trouble. If, however, the hens are heavy, have the roosts very low. Bumblefoot is caused principally by the chicks flying down from the roosts. With the heavy ones, if the roosts are high, the force with which they alight bruises the foot. This every-day bruising will cause the bumblefoot, stone bruise or felon on the bottom of the foot, and while it can be cured, it is often a tedious cure; then, the chicks are no profit while their feet are sore.

FEEDS FOR CHICKENS.

The question is often put to us, "What is the best food for chickens?" To this we can but reply: A variety of grains, giving about a third each of grain, green and meat food in the course of the day. When we are asked, "What do you feed," we feel with Shakespeare, "It is easier to tell twenty what were good to be done than to be one of twenty to follow our own teaching."

As a matter of fact the owner of a farm flock cannot feed his chickens economically without using what he has on the place. To buy a variety of grain is not always possible. We get good results from feeding what we grow. Possibly if we were compelled to buy everything we feed the prepared foods would give us better results, but the gain we make under general farming conditions would not pay for the increased cost of the feed.

This year we grow two mixed crops, one of barley and oats, the

other of wheat and oats. The chickens seem equally fond of either mixture, and we alternate the feeding of these grains. We also have a supply of these mixtures ground for cow feed. To the ground feed we add some corn meal and fill hoppers to which the chickens have access all the time. In other compartments of the hoppers we have dry bran, charcoal, oyster shell, and beef scrap.

We have a wire pocket in the houses which we keep filled with alfalfa hay. This hay is the last cutting and very short, making the finest of feed for the chickens. When we did not have the alfalfa we used clover hay, but the chickens prefer the alfalfa. As long as the field was green the chickens would almost live in it.

Our evening feed through the winter is corn. Whenever we have milk to spare the chickens get a panful; the rest of the time they get warm water. With this method of feeding we get about a third egg yield each day through the winter months from the large flocks and a half or better from the small. We find that the chickens which are housed the entire winter lay as well as those which are allowed to range through the day, provided the supply of food is kept up, especially the green food, and also provided that the litter is not allowed to become packed so that the hens can not scratch comfortably in it. We encourage exercise by shaking up the litter, giving fresh litter frequently, always having something to scratch for. Hens will not become over fat from eating the grains found under six or eight inches of litter. We use on our table porridge and bread made from grinding our own wheat, and sifting through an ordinary sieve. The coarser part of this wheat is saved for feed for little chicks; if we get more than we think we care to save, we scald a portion with hot water or milk, salt lightly and give to the hens for breakfast on a cold day. Sometimes we scald oats in the same way, and as a relish we parch corn in the oven for the chickens.

What one feeds is of less importance than how it is fed. If the chickens have enough to eat, and are given green and meat food as well as grain, they will pay well for their board though they may lack in a variety of grain.—Wallace's Farmer.

Pease Bros. Furniture Company of Los Angeles, are now manufacturing their own mattress under the name "Slumberland." The mattress is fully guaranteed, they prepay delivery charges to any point on the Pacific Coast, and they are shipped subject to approval. This mattress is advertised elsewhere in this issue.

THE OLD RELIABLE REMEDY FOR HORSES—USED AND ENDORSED IN OVER 100,000 STABLES.

Tuttle Elivir Co., Gentlemen:—I had occasion to use your Elixir on one of my horses last winter and I was very much pleased with the effect produced. The animal had fallen and bruised her leg severely, and considerable fever had set in. The Elixir was applied a few times and she recovered very quickly and completely.

I consider it the best remedy I ever used for bruises and cuts and for any other use where a liniment would be required.—M. L. Wright, President and Gen'l. Manager of the California Mutual Live Stock Insurance Assn., Los Angeles. Cal.

The March Century is notable for the number of its articles on public interests. The new President is given a prominent place in its pages, with a study, published anonymously, of his interesting personality; a picture, sketched by James A. Le Roy, of his character and methods as revealed by his work in the Philippines; and a first publication of two letters of Mr. Taft, one declining to be considered for the presidency of Yale, the other accepting his appointment on the Philippines Commission. In addition the reminiscences of "Rutherford B. Hayes in the White House" and the story of "Our Presidents Out of Doors" make the issue decidedly a "White House Number," as it is called.

The rapid growth of the business of Pomona Manufacturing Co. of Pomona has compelled it to increase its manufacturing plant. This concern has built new quarters for its foundry which is a new concrete building. This gives more room for the manufacturing plant which is one of the best in Southern California. If you are interested in deep-well pumps, you should write for a catalogue, which will be sent free if you mention Cultivator.

The Harvey Spring Co., Racine Junction, Wisconsin, has issued a folder setting forth the advantages of the Harvey Bolster Spring. This spring results in great saving to wagons and with many products, especially fruits, gives a saving in the load hauled. This spring certainly gives an advantage to every farmer using it. This folder will be sent on request if you mention the Cultivator. You should get one and read it carefully.

Smeltzer, Orange county, has been shipping cabbage at the rate of about a car a day.

Some contracts are being made for next year's hops on the basis of 9½ and 10 cents.

Polly Oil

February 6, 1909.

Dear Sirs:—

I have used your Poultry Tonic for a long time and think there is none so good. But you have one remedy, POLLY OIL, I do not feel you know its worth. I had one little sample bottle given me a few weeks ago. I used it on two cases of swell head and it stopped the swelling right away. I had one pullet on which the lump had stayed for over two months, her bill having grown crooked. but as she was a pet I could not have her killed, but could not drive the lump away until I got the sample of Polly Oil. It then commenced to go away, and in a few days it was nearly gone. I have cured every one since that showed any signs of such trouble. I have used all I have and do not want to be without it.

Very respectfully,
FANNIE L. E. WEBBER,
Pasadena, Cal.

If not sold by your dealer send the price, 50 cents, and we will send you a bottle, prepaid. WEST COAST MILL, Los Angeles, Cal.

WATER GLASS FOR EGG PRESERVING

Why sell eggs at 15c a dozen? Eggs kept in this water glass will keep 12 months or more and are as fresh as new laid. Sold in 25c tins for 150 eggs and $1 tins for 1200 eggs. Egg preserving baskets with cage and cover $1 each. There is only one kind of water glass suitable for this purpose and it is on sale at West Coast Seed Co., 115 West Seventh St., Los Angeles.

$100 Cash Free to You

I sell "SUCCESS" Incubators on trial. I guarantee to refund the money after you use the machine if you do not find them to be exactly as I claim. No other company in this state will do this. Up to this date March 15th, not a single customer has asked for his money BACK either on a "SUCCESS" INCUBATOR or a "SUCCESS" Brooder. I will give you $100 cash if you prove this statement is not true. Is this a good record? Does it not prove that these machines are what we claim them to be? Does it pay you to spend from $5 to $20 more than we ask for an Incubator that will positively give you a good hatch EACH and every time. Some incubators hatch good once in a while, ours hatch EVERY TIME if the eggs are reasonably good. I make Fireless Brooders that will raise every healthy chick. I handle over 240,000 chicks yearly through the Pioneer Hatchery, I know how to BROOD them. Send for FREE catalogues and circulars.

General Agriculture

THE DURUM WHEATS.

THE durum wheats have been grown in this country in insignificant quantities for about thirty-five years, but until 1900 there was no organized effort to induce the extensive cultivation of these grains. During that year the Department of Agriculture sent a representative to the durum-wheat sections of Russia to investigate the conditions favorable for durum-wheat production.

As a result of this investigation a large number of varieties were introduced by the Department of Agriculture. They were distributed to various stations of the Great Plains area, where the conditions are very similar to those found in Russia and Algeria, from which latter country a number of varieties have also been introduced. At first these grains were received with but little favor, in spite of the fact that they produced excellent yields and exhibited remarkable rust-resistant and drought-resistant qualities. Their rust resistance is especially important. This was particularly noticeable in the rust epidemic of 1904, when so much damage was done to the common varieties. The later popularity of durum wheats in this section is largely due to their great resistance of rust in this epidemic. They are, in fact, coming to be considered as the only reliable spring varieties to grow in sections where rust is frequently prevalent. Their drought-resistant qualities are constantly being brought to notice. In Texas, Montana, California, Utah, and in many other sections where severe drought occurs they are outyielding all other spring varieties and in many instances are rivaling some of the leading winter grains. It has been found that these wheats are particularly adapted to the Dakotas. About 80 to 85 per cent of the durum wheat produced in 1907 was grown in this belt.

Growing Popularity of Durum Wheats.

The opposition to the durum wheats, especially among farmers, is rapidly disappearing; in fact, these wheats are even being grown in sections to which they are not adapted and where they should not be planted. They have been taken to Minnesota, a section wholly unsuited to their production because of the high precipitation and the excessive humidity of the atmosphere. They are preeminently grains to be grown where the summers are hot and the atmosphere dry. The farmers of Minnesota, however, have come to value the durums because of their rust resistance rather than because they are otherwise adapted to that section. In some parts of the state they are displacing Fife and Bluestem. For this reason the millers are inclined to oppose them very vigorously and in this they are fully justified. The U. S. Department of Agriculture has never recommended the growing of durum wheats in the humid regions.

The durum wheats became prominent commercially in 1903, when 6,000,000 bushels were produced. Their production has steadily increased up to the present time. The crop of 1906 was between 40,000,000 and 50,000,000 bushels; that of 1907 was even greater, notwithstanding the unfavorable crop conditions in the Dakotas. One of the striking features in favor of the durum wheat is the growing demand for it in both foreign and domestic markets.

Of the crop of 1906, some 6,000,000 to 10,000,000 bushels were consumed in the mills of Minneapolis in blending with other wheat; 20,000,000 bushels were shipped to foreign markets, some of it going to Russia, whence it was originally introduced; some 5,000,000 bushels were used for seeding the crop of 1907, and the remainder was used by small mills throughout the country. Before the harvest of the 1907 crop the 1906 yield was entirely consumed. The 1907 crop is going even more rapidly. One man, representing a foreign firm, purchased last December 1,500,000 bushels for export. This is the largest quantity ever bought for export trade at one time by one man.

The difference in price between the durum wheats and the No. 1 Northern is becoming smaller each year. Durum wheat now sells for about 2 cents more than No. 2 Red Winter on the Chicago market. The attitude of the northwestern grain journals regarding durum wheat is rapidly becoming less antagonistic, and even the millers are beginning to concede points in its favor. As the millers perfect their methods for milling these wheats they invariably recognize the merit of the durums, especially as blends with the softer varieties and as a source of semolina, or "macaroni flour." It seems certain that the durum wheats are destined to become the leading spring varieties throughout the whole arid West.

PLOWING THE ORCHARD.

(Continued from Page 309.)

furrow not to make it at all deep. We do not in the wet weather object to having a dead-furrow to hold the water away from the trunks of the trees. This dead-furrow in the center is often filled with water for several days at a time in very wet weather.

10:—No, we prefer to keep the weeds off by hand as there are no active roots in this space during the mature life of the tree. Coarse ditch sand is plentiful in the creek on the ranch and we use it at the base of the trees as it acts as a mulch and helps to keep the ground soft without much cultivation.

11:—No, except the same result may be secured in the way we like to manure the vineyards, by putting the manure in between the rows in a trench plowed and V'ed out twenty to twenty-four inches deep, filled to within eight inches of the top and then the earth thrown over the mass by the plow.

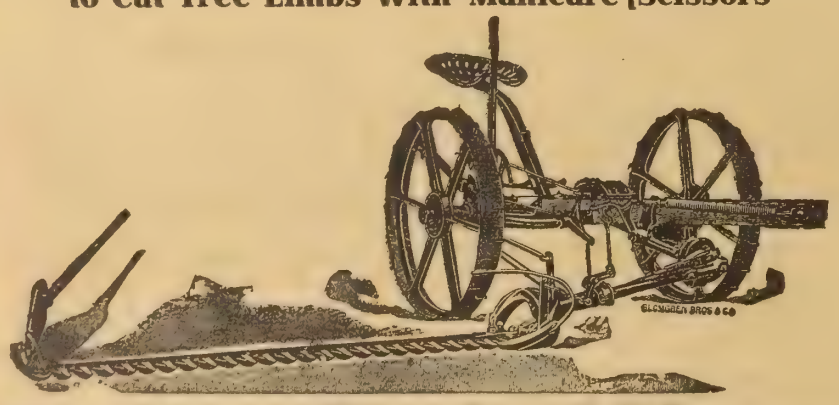
12:—The plow, while it does make plow sole and has to be used at varying depth, has not been superseded in our neighborhood. We all had it bad, this fever of cultivating with different kinds of tools and leaving the plows stand idle. We tried it with the result that the vines were less vigorous and gradually the plows came back into use. It is mighty hard to fool old Nature after all, with new tricks. To find out why the deep cultivating did not answer, we dug two pits just twelve feet apart to see what was the matter. These pits were three feet deep and about three feet square. The land that was cultivated only

Did You Ever Stop to Think

That the Lightest Looking Mower Is Very Apt to Cut Heaviest;

ALSO

That Only a Very Foolish Person Will Try to Cut Tree Limbs with Manicure Scissors



The New Standard Mower

All power in a Mower originates from the grip of the wheels on the ground,—the firmer the grip the greater the cutting power.

The 5-foot New Standard Mower weighs 825 pounds. The entire weight of the cutter bar (while cutting) is transferred through the suspension spring to the main wheels. The bar is neither pulled nor pushed,—it is carried—an exclusive Standard feature.

The power thus secured is transferred to the gearing through the mechanically perfect wheels, found only on the New Standard Mower. The gearing develops high speed without undue strain and passes the power to the knife. The knife works in our famous curved Cutter Bar,—the only frictionless knife channel made.

These are a few reasons why the New Standard Mower is the most powerful cutting mower made.

A folder giving full detailed description of the New Standard Mower and our other Haying Tools will be mailed free on application.

Newell Mathews Co.
200 North Los Angeles Street
Los Angeles, California

looked denser and was dryer and less mealy to the hand. It showed at twelve inches a denseness that was almost too hard to cut out readily. The other side of the drive where the same land was in an orchard that was plowed and harrowed in the regular way, the soil was moist and no dry streaks, and seemed mellow to the touch. Before we stopped plowing in the vineyard, both pieces had received exactly the same treatment and the same amount of manure. The two were only twelve feet apart and the difference was not noticeable before the change in way of handling in the growth of the crops. We then resumed the plowing of the vineyard and after the second year the normal conditions had come back. We again had pits open in the same spots when the soil conditions were the same as to moisture. Since then we have held by the plows.

One man in the neighborhood followed the using of the cultivators for several years longer. This was a company vineyard and then he was discharged for not securing results. The new manager went to plowing and harrowing and cultivating in the regular way and has held the position ever since. The vineyard looks altogether better and this man has held his job, so that evidently his employers are satisfied with the returns. One vineyard that was never properly cultivated until it was fifteen years old was sold very cheaply, as it was considered as only good for half a ton of raisins to the acre. The man that purchased it went to plowing and cultivating with wholesome vigor, the crops increased until it produced the second year close to two tons of raisins to the acre. The plow so far has proven the best tool; while I know it makes plow sole and is more expensive, still we have learned to handle that plow sole by plowing a little deeper the alternate years and by turning under humus to hold more even conditions of moisture, and we know this way does grow good crops. —M. E. Sherman.

COUNTY CONTROL OF TREE PLANTING ON COUNTY ROADS.

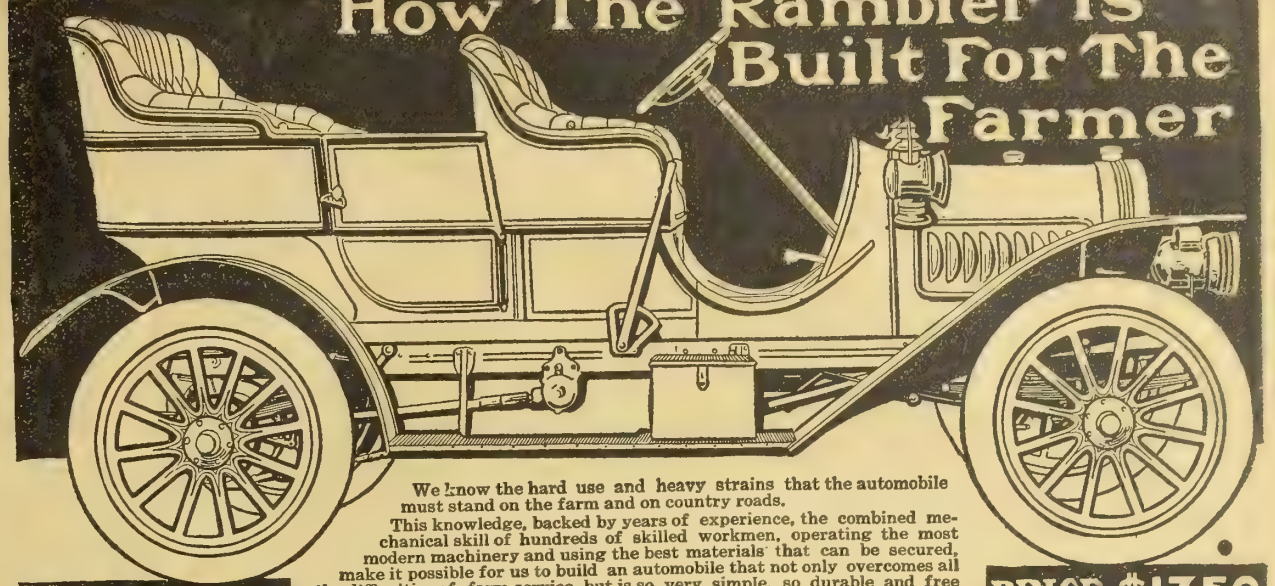
(Continued from Page 313.)

eign trees well suited for the purpose, which in a brief time would transform the general appearance of the country roads, where used. To have the country highways of California bordered with shade trees would add a distinction not yet secured by any country, properly supplementing her already distinguishing features, besides the constant pleasure they would give to travelers.

In the meantime, let neighborhood and village associations do what they can towards beautifying their immediate vicinities, by planting roadside trees, even if but a mile or two. Commercial organizations and improvement societies of our cities can well afford to give attention to beautifying the leading thoroughfares entering their towns. Redlands is already planning to plant the entire length of the street between that city and Highlands, which if properly carried out will give a splendid object lesson to other cities.

But the main object in writing this article is to direct attention to, and urge the importance and practicability of tree planting along our country roads, by the county governments.—J. H. Reed, Riverside.

How The Rambler Is Built For The Farmer



MODEL 41

PRICE $1350

We know the hard use and heavy strains that the automobile must stand on the farm and on country roads.

This knowledge, backed by years of experience, the combined mechanical skill of hundreds of skilled workmen, operating the most modern machinery and using the best materials that can be secured, make it possible for us to build an automobile that not only overcomes all the difficulties of farm service, but is so very simple, so durable and free from repairs that the cost of up-keep is below that of any other car.

How well we have built this car is best told by the service the Rambler is giving to thousands of satisfied owners.

One owner writes us:—"I spend less for oil and gasoline than the cost of feeding a horse." Another says:—"The cost of up-keep is no greater than that of the simplest piece of machinery on my farm." We have scores upon scores of such letters in the same vein, all telling the same story, all proving our claim how little it costs for the daily up-keep of a

Rambler

THE CAR OF STEADY SERVICE

We wish it were possible for you to visit the Rambler factory. It covers 15 acres of ground, and is the largest and best equipped automobile factory in the world. It is under the personal supervision of a man who has had over thirty-five years of actual manufacturing experience.

We wish you could see how the Rambler is built; see the materials which enter into its construction, how the different parts are tested, how each Rambler is tested before shipment. You would realize then why 14,000 Ramblers are in the hands of owners, and we have yet to hear of one that is worn out.

We want you to examine this Rambler; see the ease with which the luxurious 5-passenger tonneau can be removed and the torpedo deck substituted, making a stylish 2-passenger roadster of medium weight. Then see how quickly the Torpedo deck can be removed, leaving a handy utility car with which you can carry produce to market, milk to the creamery, parts of farm machinery to the blacksmith's, trunks to and from the station, bring seed and supplies back from town, and haul the thousand and one miscellaneous things that every farmer has to have—things too bulky or too heavy for his buggy and too small to require the big wagon.

We want you to know about the Rambler double opposed motor; note how it is entirely enclosed, together with the transmission gear, making the power plant a unit.

Then see how all mechanism is protected from injurious road materials by the shield of light metal that extends under the entire bottom of the car, the ease of control, the small cost of up-keep, the large wheels, the big tires, the full elliptic springs, the comfortable cushions, the highly polished durable finish, the wonderful hill climbing power, the absolute safety on steep grades, the starting and stopping without jar or jolt, the ease with which parts are reached, are but a few of the many reasons why the **Rambler is the standard car for farm use**—the choice of the American farmer—the most exacting and discriminating buyer in the world.

Everybody who has ever ridden in a Rambler has expressed astonishment at its power, silence, smooth running and easy riding qualities

Write today for our interesting and instructive farm folder. It tells you what Rambler owners think of their cars, why they chose the Rambler and what pleasure and profit they derive

Don't fail to write today for Farm Folder 156.

Queries and Replies

Questions to be answered in this department should be received at this office one week before reply is expected. Write plainly on one side of the paper and sign full name and address. Unsigned communications receive no attention.

Alkali.

Please advise regarding preparing 40 acres of dark loam soil for alfalfa seeding. There are a number of alkali spots from 15 to 30 feet square. Will lime, air slaked, be of use in reclaiming? How much per acre should be used? Is gypsum better? Do not expect to irrigate this year. It is now very wet and will seed as soon as land will bear it.—W. M. M., Corcoran.

Lime would be of no value in reclaiming the alkali land. Gypsum is of value providing the alkali is of the black variety. In such case it turns the black alkali to white alkali which is much less caustic and more easily washed from the soil. The best plan of all is however to under-drain which while expensive at first, puts the land in magnificent condition for years to come. If gypsum is used apply 400 to 500 pounds per acre. We note you say you do not expect to irrigate this season, but if you anticipate irrigating later it will be well to check the land so that water may be applied when you need. In such case make the checks as far apart as possible and say about 18 inches high. Make them so broad that the machine and rake may readily pass over them without inconvenience. If you will refer to the Cultivator for January 21, the first page article, you will note an article on the effect of limes on soils in which alkali is to a certain effect treated of.

Leaks Her Milk.

I have a cow that gives from 4 to 4½ gallons, but about the middle of the afternoon the milk begins to flow and unless I take time to milk her I must lose considerable milk. I found in the July Cultivator, 1907, a remedy in a common rubber band on the teat, but I do not think that would do in this case as the teats are large and fleshy.—J. W. A., El Monte.

This cow should be milked three times a day to relieve tension on the udder. She is probably able to give much more milk than she is at present producing. The rubber band remedy has not been a great success with us. It is applied by using a visiting card under it to prevent strangulating the end of the teat. If any one has given you any other remedy I would be glad to know what it is. We always milk any cow that leaks her milk oftener, and find that the successful way of ridding her of the extra milk.—M .E. S.

Milch Goats.

Can you tell me of any one in this State who has a good milk goat for sale? Also what are the markings or points of a milk goat. There are several different kinds of goats, I know, but I do not know one kind from another. Thanking you for the many helpful articles in the Cultivator.—H. A. S., Lodi.

It is impossible to give you any satisfactory information as to the price of purchasing milch goats. The imported stock which is the heavier milk-producing strain, costs such exorbitant prices in expressage and import duty that the price is almost prohibitive. We have been told that $150 is about the lowest price for such imported stock. Of course some of this stock has been introduced and crossed by the indifferent stock and some fairly heavy milk-producers have been bred; but the demand for these has been so strong that the prices are still high. Mr. H. A. Wood, of Pasadena, also Dr. Jas. H. Hester, of Santa Barbara, have had some experience in handling this stock. It is possible they could give you more particular information. There is also, we believe, quite an extensive dairy near Hollister, but the name of the owner we cannot give you. The different varieties of goats are the Maltese, bred on the Island of Malta in the Mediterranean; the Toggenburg and the Saanen, also a Swiss goat; the Nubian from Egypt; also some others. Of these the Toggenburg is perhaps the most popular in this country.

Millet.

I lately saw something in your most valuable paper in high praise of millet as a feed for chickens. What kind is recommended and where can I get seed? What is its relative value as compared to other grains?—W. R. T., Calistoga.

The seed can be secured from the seedsmen advertising in the Cultivator. The German, the Hungarian, and the common millet are the varieties. It requires from 30 to 40 pounds per acre. Millet seed resembles oats in composition, and Henry says in his "Feeds & Feeding:" "It cannot successfully compete with Indian Corn in sections where corn is successfully grown." "It has a higher proportion of albuminous and a higher nutritive ratio than oats, but less oil. It is one of the best rations for horses, being adapted to the development of muscular strength." For little chicks we do not doubt it would be valuable.

School children at Santa Rosa spent Arbor Day this year planting Shasta daisies.

Overfeeding.

I have a calf one month old; was strong and healthy till a week ago, when it would lie flat out on the ground refusing to move when touched, and in afternoon it looked as if just fed; it also vomits its food many hours after feeding and will not drink its usual amount. It has been having 10 quarts fresh warm skim milk in two feeds.—M. B. M., San Diego.

Whenever a calf becomes dumpish you may safely conclude it has some indigestion. Give this calf half the amount of milk with a rennet tablet dissolved in water added to it. Gradually increase the milk; I would not, however, feed a calf of this age more than three quarts at a time. The amount of ten quarts a day is enough for a three or four months old calf. A little dry bran with salt in it in a rack at one side will be helpful after the calf is three months old.—M. E. S.

Possibly Tuberculosis.

We have a Jersey cow, eight years old, fresh last September, gives about 3½ gallons a day, milk very rich. She is never fat but is in fair condition. Occasionally the right hind quarter of her bag becomes swollen, stays so for about 24 hours, when it passes away. This has occurred about four times in the past three months. She is fed alfalfa hay in the morning, is then staked out on green barley; is always treated kindly and handled carefully. I noticed in the last Cultivator that such swellings indicated tuberculosis. How do you proceed to have a cow tested?—Subscriber, San Bernardino.

Have you ever investigated cause for this trouble? I had a cow that was troubled in this way and found that she twisted herself in the stall so that she pressed the udder against a slat that had been put in the side of the stall as a protection against the cows slipping. Examine into the surroundings and then if you are satisfied that it comes from internal causes, if you will drop a line to the University Experiment Station at Berkeley and ask for full instructions they will send them to you and also the tuberculin if you will agree to give them the records. Should you not care to do this the local veterinarian will probably test her for you for a couple of dollars.

Fungus on Lemon.

I am addressing to you a cutting of a young lemon tree from my garden. The only one I have. Yesterday as I passed by it I noticed the withered appearance of the twig and cut it off when I saw what appeared to me like a fungous growth on it. Can you inform me if it is anything serious and if so, what is the remedy? There is no other sign of the growth on the tree.—N. P. Nielsen, Haywards.

The lemon twig is affected by a fungous growth which usually propagates in the soil, although it sometimes affects vegetation above ground. In the present connection it is not a serious matter and your correspondent does not need to apprehend that it will cause any severe injury to his tree.—Ralph E. Smith.

Silos.

We are in the dairy business, and are contemplating the building of cheap durable silos. We have considered making a 20x30x100 beet silo of cement and stone in the side of a hill, so that we can deliver the silage from wagons or a chopper directly to the top. We have everything on the ranch to build such a silo, but cement. How practical do you suppose such an affair would be? Do you know of anyone who has had experience with a silo of this sort?

Would stock beets be a profitable silage to the extent of about 100 tons? We are considering the planting of several acres of such beets.

We would thank you for space enough in your paper to explain as thoroughly as you may, the value of stone silos and beet silage.—Panba Ranch Co., Temecula.

I do not understand the dimensions given, but for practical uses the diameter of the silo should not exceed 26 feet and the pits must be one and a half times as deep as they are wide at the least. The depth may be increased to advantage. A silo that is shallow rather than deep will not preserve the silage. Even in a silo of the proper depth the silage in the bottom is better than the first ten feet; owing to greater weight it is better cooked in the heating up process.

Silos are very successfully built of concrete and if you will send to the Government Dept. of Agriculture a bulletin can be secured that will give drawings and plans for the same as I could not give the detail in the paper without encroaching on too much space. I can see no special use in hauling the feed to the top when the same power that elevates the corn is used to cut it. The stone, brick and concrete silos have the advantage of being permanent structures while the wooden ones will last twenty to twenty-five years if kept in good order.

Stock beets are profitable for feeding and the tops may be siloed with good results. The roots are hilled up and fed as needed, or may be left in the ground and taken up as needed. The corn crop is cheaper with us than anything we can grow so that we do not grow beets any more, but can assure you they pay well.—M. E. S.

We think the circular silo is much to be preferred to the 20x30 shape suggested by the enquirer. A corner in a silo is most objectionable. As Mrs. Sherman notes: "Why haul the feed up the hill?" Yet if the feed is grown on the level with the top, that might be an ideal feature and save some little power in elevating it.—Ed.

Butte Valley.

Please state where Butte valley is. What is its temperature, and is it effected by frost in winter? Would the place have to be drained? If so please tell me what it would cost to drain five or ten acres? If I have my own irrigation system how strong would the engine have to be? What crops grow in the valley? Is it too cold for oranges?—B. P., Los Angeles.

Butte valley is in Siskiyou county and at an altitude which will give you frost probably eleven months out of the year. There will be no possibility of raising oranges in that section. As to draining, that would depend on immediate situation and could only be told by examination. The cost of draining depends on so many things that we can not give you any intelligent answer. The size of engine to lift irrigation water depends on the amount of water which you need and the distance to be lifted. The valley is principally given over to grazing, but it is probable that apples and some hardy fruits will do well.

Page Woven Wire Fence Co. Box 114X Adrian, Michigan

Orange Seed Bed.

What number of orange seed should be used to plant a bed 50 by 50? What formation of soil is best and how should the bed be prepared? Should stable manure be used? What kind and how much fertilizer while the trees are growing? What is best time to plant the seed? What kind of seed is best? Will trees do as well in sunshine as if partly shaded? Can you give name of party who can furnish seed?—H. A. M., San Bernardino.

You would need from 20 to 25 gallons of seed for the space you refer to, which would produce you about 150,000 trees. A good loam soil which is rich enough for best garden production will be all right for orange seed beds. The bed may be prepared in open ground or in flats as you may prefer. Of course if not rich enough it would be too late for this season to get it properly enriched and in condition for planting the seed. For seed bed work you do not want to do any heavy manuring after planting the seed. As a mulch, fine cow manure is probably the best. This may be sifted over the seed after planting. The seed may be plantel now or before the end of May. The kind of seed which is best to plant depends on the locality in which the orchard is to be planted, or at least it is so thought by many. If the land is low and damp the sour stock is probably the best as it is less liable to gum disease. We doubt very much however your ability to get that amount of sour stock seed this late in the season. We would suggest however, that, planting as large a quantity as you anticipate, you should secure the services of some one who understands this work as an aid at start at least. The seed bed should be protected from the direct sunshine which protection is also valuable in case any frost threatens. Seedsmen advertis-

Legal Queries

Edw. L. Payne, attorney, 301-304 Douglas Building, Los Angeles, will answer legal queries in this department.

Immediate mail replies cannot be given except where fee to Mr. Payne is paid. When replies are wished in Cultivator address query to 115½ N. Broadway, Los Angeles.

Right of Way for Water.

Suppose A lets B run water across his land once does this give B any right of way for ditch?

Suppose B paid A for being allowed to run water but has no deed to right of way, can B then hold ditch in future years?

Can B force A to sell him a right of way for a ditch across his land, or can the canal company compel A to let him through? Said land belonged to one party and was located by first owner, but when sold out in small tracts no ditch right was mentioned in deeds. B can get his water another way.—O., Selma.

No, it takes five years adverse use and possession to give B a title or right of way.

No, for the possession of B would be such as to recognize the rights of A, and not adverse to A.

B can not force A to sell him a right of way for a ditch across A's lands if B desires the ditch for his private use, but B or a water company or canal company might condemn a right of way across A's lands for a ditch or canal if the same is for public use, or for the purpose of supplying a neighborhood with water, or for drainage purposes, or for other uses particularly mentioned in the code.

Condemnation proceedings rest upon the right of the people or Government to take private property for public use, and must be instituted and prosecuted in the manner prescribed by the statute, and of course, it would be necessary to consult your lawyer as to your rights in the matter in a case of any such proceedings. The fact that B has an opportunity to get water onto his land without passing through the land of A, would prevent B from condemning a right of way across A's land, if other facts or circumstances existed which would otherwise entitle him to do so.—E. L. Payne.

Trees Near Line.

I have an orchard that has green timber growing on either side, some large pine trees growing close up to line that injure about two rows of my fruit trees. Can I do anything with parties owning adjoining land in regard to having trees cut down?—Subscriber, Rocklin.

You may not have the trees cut down as they belong to the adjoining owner, and you probably have no redress for the injury to your trees, for while overhanging branches are a nuisance, which may be cut down by injured owner, he has no right to cut down the tree itself, where the tree stands entirely on the adjoining owner's land.

There is a decision by the Supreme Court of California, which indicates that you might possibly have damages for the injury to your trees in an action brought for that purpose, but the point is not decided.—E. L. Payne.

Damage from Storm Water.

What is the law regarding storm water from the foothills when, in order to grade up orchard lands, it has been turned from its natural channel into the roadside? May a rancher turn such water onto his neighbor's roadside? May one county turn it into another? Should it be carried on the upper or lower side of the road? —A. M., Whittier.

"The owner of higher land has no right for his own relief, to the injury of the owner of lower land, either to divert surface or storm water upon such lower land, over which it would not naturally have flowed, nor has he the right by accumulating the surface waters upon his own lands in ditches or other artificial channels, to precipitate them upon his neighbor's land in larger quantities or in different form from that which they would have had or taken in the course of nature." Therefore, the party upon whose land the water was turned in the grading of orchard lands, as indicated in the query, might have damages for the injury resulting. Had the injured party acted in time, he might have enjoined the grading of the orchard lands.

One has no more right to turn storm water from its natural channel onto his neighbor's roadside, if it will thereby injure his neighbor, than he has to turn it directly onto his neighbor's land, and a county has no greater rights in respect to turning water from its natural channel, where it will do injury, than has an individual.

The question as to whether or not water should be carried on the upper or lower side of a road, is eliminated by the foregoing answers, as the storm water must flow in its natural channel no matter where that be, if a diversion of it will cause injury.—Edw. L. Payne.

WE INTRODUCED

Crimson Winter Rhubarb

Into New York and Philadelphia, and other Eastern Markets. Let us tell you more about our methods of introducing California Products under a Guaranteed Label.

We understand eastern conditions, eastern markets, eastern people, their likes and dislikes.

How to put up shipments in an attractive manner. We do not dump our goods on the Eastern Commission Houses and take a chance on getting a price. No! We go right out and create a demand among the high grade dealers under a special brand, and That Brand is a Guarantee that the goods are special first class. Our men are working among the Eastern Trade all the time.

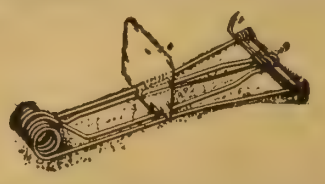
EVERY GROWER AND SHIPPER

No matter what their present arrangement may be, should write us for information, for by our plan you receive the best prices paid in the Eastern Markets.

THE PHALANX COMPANY
513 Chamber of Commerce Building
Los Angeles, Cal.

Eastern Offices, Philadelphia and New York. Members of Los Angeles Chamber of Commerce.

MACABEE GOPHER TRAP



Small, simple, sure. At all dealers. If your dealer does not handle same, send 20 cents in stamps and mention your dealer's name and get sample by mail postage paid at special rates. Manufactured by.

Z. A. MACABEE, LOS GATOS, CAL.

The California Mortgage Lifter

Great Profit from Crimson Winter Rhubarb Which is Putting It in the Money Making Class as No Other Similar Product Has Ever Been Placed

RHUBARB culture has widened its field to such an extent and has attracted so much attention from those who are ignorant of the details of its culture that many queries have come to this office asking for more complete details of its culture. Formerly growers having a spare corner of the ranch which nothing else particularly demanded, would consider it a fitting place for a few roots of rhubarb but the promise of great profits which many growers are finding have been fulfilled is increasing this interest so that instead of a corner the principal feature of some ranches has become the rhubarb garden or field as it may be called.

The Rhubarb King.

Believing the place to get the most reliable information was to go to the most reliable and best fitted source to procure that information, an interview was sought with Mr. J. B. Wagner, the rhubarb king, at his delightful home in one of the most attractive residence sections of Pasadena, the home of millionaires.

Home of Culture.

Mr. Wagner's home is a typical home of culture, being filled with musical instruments and other indications of cultured life. It is not palatial but one of those places which give one the restful feeling all true homes should.

The object of the interview was of course to touch upon other things than the home life of this man who has done so much to advance the commercial interests of California by improving new strains of Crimson Winter Rhubarb. It was in fact to secure at first hand some information as to culture and localities where greatest success may be secured by this product which has been called the "California mortgage lifter." Therefore, while we might have been interested in securing a closer insight into the life of this man, we at once proceeded to secure such information as possible regarding the cultural methods.

Location.

First, as to locality, Mr. Wagner always advises care in selecting location. As a rule he says to notice where the orange does well; there the rhubarb is at its best. There are many other sections where it has done well and paid handsome profits, but in the citrus section conditions seem to be more nearly perfect.

Soil.

In the matter of soil, Mr. Wagner says the range is exceedingly great. He would prefer a warm, sandy loam, but remarkable results which have brought great profit to the owner have been secured in heavy adobe land. Where the heavier soil is used, liberal applications of stable manure aid in putting it in better condition for the best results. It has done fairly well on a very light sandy soil, but in this case of course it must of necessity have good supply of fertility which makes more expensive culture.

Fertilizer.

Remarkable results have been secured without the expenditure of any money for fertilizer, but experiments have been tried by Mr. Wagner in which the addition of 10 loads per acre, or the expenditure of say $25 on soil of only very low fertility has brought the satisfactory, even remarkable income of between six and eight hundred dollars from the acre. Hence it is readily seen that if $25 worth of stable manure insures a crop of such remarkable profit the money is well spent if only for the feeling of security which it gives. Commercial fertilizers which are rich in nitrogen succeed fairly well, but are not so desirable as the stable manure.

Water.

Points on irrigation are hard to give because it depends entirely on soil and climatic conditions. For instance, in the Coachella valley one grower gave irrigation every three or four days during the first summer after planting. The return for this outlay of water was of course very strong plants with a big crop.

In the following year the irrigations were much less frequent—every three or four weeks—and plants still did equally well. In contrast with that, we may say that plants in Ventura county near the coast have been carried through the first season, with not more than three or at most four irrigations throughout the entire season and none whatever in after years. From this great range it will be seen that conditions in each locality must be studied before an intelligent answer can be given.

On the question of water, the last few months have given some lessons. On this point we are permitted to quote from a letter by Mr. Shoemaker, president of the Phalanx Fruit Company, to Mr. Wagner, as follows: "We have found that water adds greatly to the flavor, color, and shipping qualities. That which has been well watered will keep much longer, without ice, than that which has not been watered.

"I have just received a sample box of five weeks old rhubarb from Ventura, where it has plenty of water. It certainly looks fine; would like you to have seen it, but I believe water will do the same thing anywhere."

Culture.

The question of culture is sufficient to call for another article, which will be given later. For the present we may say, however, that this wonderful plant may be planted at almost any month of the year. In fact it has been, in various sections of California, but the best results have as a rule been had from planting from the present on through to the end of May or possibly June. While chatting with Mr. Wagner, a customer called and took away a small parcel of plants for immediate planting. These will get thoroughly rooted and be in good condition to give a fine crop next year as well as producing some fruit during the time of growth.

A word as to the commercial quantities and the efforts to introduce rhubarb on the market. Last fall the Phalanx Company was organized with head offices in the Chamber of Commerce building of Los Angeles, to ship this product to Eastern markets. The company has over 100 acres of rhubarb. This, with what is consigned to them, gives the company a good supply to ship to the Eastern trade.

The Phalanx Company have an ad in the Cultivator, so those who have rhubarb for market should write that company and secure shipping instructions.

Regarding the demand, Mr. Wagner recently remarked:

Los Angeles has become a good market; they now use about 10 cars per week during late spring and winter. No doubt it will be some time before we will be able to supply home demand, while the demand in the East will probably never be supplied owing to the fact that the area where Crimson Winter can be successfully grown is limited to certain sections in California and Arizona and Texas.

Another thing which did more to stimulate the market than any other was the organizing of the Southern California Rhubarb Growers; this organization acts in the same capacity for rhubarb growers as the Orange Exchange does for the orange growers.

Everyone interested in the cultivation or marketing of one of California's most profitable products, should detach the coupon and send to Mr. Wagner, and receive information as to prices of plants, whether they are adapted to your section or not and other interesting particulars of value to every one.

State Horticultural Commissioner Jeffrey has issued a quarantine notice putting a ban on receiving of cotton seed from that section of Texas infested with the cotton boll weevil.

HIGH PROTEIN MEATS.

Manager J. E. De Young, of the Geo. H. Croley Company of San Francisco, has arranged with the Globe Mills of Los Angeles, to act as the agency for Croley's High Protein Meats for Los Angeles. The demand from poultry people for the reliable foods of the Croley Company is increasing. The Globe people will doubtless still further enlarge the field in which these goods are used.

Household Department

MALONEY'S ST. PATRICK'S DAY HAT.

Fer three sixty-four—and in lape-year wan more—
Av the days av the long, lonesome year,
It hangs all aslant in the closet beyant,
With the sorrer caller ter cheer;
The linin' is tore and the band is all wore,
An' 'tis gray as a grandfather rat,
An' the dust settles down on the brim and the crown
Av Maloney's St. Patrick's Day hat.

It was tony and foine in the year forty-noine,
An' they called it an elegint tile;
But ye take it today, and perhaps ye moight say
'Twas a bit antiquated in style.
The brim, it is true, is a taste out av skew,
An' 'tis shedding its fur loike a cat;
An' there's spots here and there that is scraped a bit bare
On Maloney's St. Patrick's Day hat.

The dint in the roof is the place where the hoof
Av O'Brien's fool hoss put a kick;
An' that hole that looks bad is a mix-up it had
With a Donegal b'y and a brick;
Thim creases round there on the side show ye where
Big Hogan sat down on it flat.
Sure, a vet'ran, no less, like its wearer, I guess,
Is Maloney's St. Patrick's Day hat.

An' it hangs on the hook in its dusty ould nook
'Till the night of the sixteenth of March;
Thin 'tis took down and rubbed and most mortially scrubbed,
'Till it shoines loike 'twas polished with starch.
And thin, the next day, it is thrimmed up so gay
With the shamrock and green and all that,
If ye don't want to foight ye must swear 'tis all roight—
Brave Maloney's St. Patrick's Day hat.

Ah! there's years not a few since that cady was new
An' Maloney was proide av the place;
Now the hair that was red is snow-white on his head
And the wrinkles are thick on his face.
But his heart is still young, loike the brogue on his tongue,
And the p'rade wouldn't start without Pat,
Fer we think it looks grand whin it follers the band—
Ould Maloney's St. Patrick's Day hat. —Puck.

GRISETTE'S NINTH LIFE.

"CHUT!" said Mere Barbizon, shrugging her wizened little shoulders under the faded calico blouse. "Talk not to me, messieurs. I tell you Grisette must be killed entirely. Oh, but yes, entirely. Already I have given her away no less than six times. Thrice to the forester's wife, a careless one, she, who lets her come back always to me again. Thrice to Maitre Perrin up in the village yonder. Ah, the miser! One could not blame Grisette for not stopping longer in a house where there was no meat, not even on a feast day. And once I lost her, pardieu! It was in the hills the time when I went to make the little visit with my daughter. Grisette awaited me on the doorstep when I returned. La, la, she sat there licking her paws with the air of one who was always welcome. Once again she lost herself. Ah, but attendez, messieurs, she really found herself again. Of that you may be sure. It is impossible really to lose Grisette, she who eats more of my food than a man, who expects always the bonnes bouches of my table. Oui, oui, messieurs, this time it is impossible that Grisette comes back. I will no longer furnish her with comforts. If she were a dog now—but a beast of a cat, non, it is impossible."

Jack Tilton and I had run across Mere Barbizon on one of our painting trips through Normandy in early May, and now it was late June, and we still lingered under her clean, but otherwise uninviting roof, held to the place by the fascination that this particular part of Normandy always has and always will have for painter folk.

Nor were we partial to Grisette, the huge gray cat, that had—so she averred—become the bane of Mere Barbizon's existence. Once she had whisked her tail across a study of coast, which I thought particularly fine, and which I had some idea of sending to the salon, and once she had played havoc with Jack's brushes. No, we would have no reason to regret Grisette, but we wanted to see fair play. Your French peasant has a heart of flint at times, and Mere Barbizon was no exception, as we had found out on more than one occasion.

Jack, who was lazily cleaning his brushes, looked over his shoulder at this point, and said between the teeth that held his pipe: "See here, Mere Barbizon, I'll get rid of that fat rascal for you. This very night, after dark, eh? And it shan't cost you a sou."

"Tiens, Monsieur Tilton, what would you do with the cat, eh!" asked the old woman, anxiously.

"Oh, I'd drown her," answered Jack carelessly. "A good big bag, a little coaxing, and we'll have her fast enough. Then we'll row out to the nets, you and I, and drop her overboard. Adieu, Grisette! See?"

"Bien," muttered Mere Barbizon. "I go at once to find the bag."

It was growing dark when Jack, carefully carrying the bag over his shoulder and followed by Mere Barbizon and myself, an amused onlooker, marched down to the beach and manned a little skiff with his motley crew. "Sit there," he called to Mere Barbizon, "where you can watch to see that Grisette plays no more tricks on you."

Silently we pulled out upon the silent water, gray now as a dove's wing and growing grayer with the advancing dark. Now and then a sigh broke from Mere Barbizon, but whether at the beauty of the night or as preliminary to the sad rite about to be performed, it was impossible to tell. Her wrinkled chin was huddled in her hands, her eyes were fixed on the bag at her feet. If she had not been ashamed to show emotion over a creature that she herself had condemned to death I think she would have given poor Grisette at least a farewell pat.

Presently Jack stopped rowing and pulled in his oars. "The time and the place," he said, solemnly uncovering. "If you have words to say to the about-to-be-departed, Mere Barbizon, say them now."

"Tiens! What have I to say" murmured Mere Barbizon. "Has she not always had the best? I have no reproaches, I, for one who has eaten the very roof from my head, the floor from my feet. Mechante! Let her go,

The Above Label is a Guarantee of Goodness

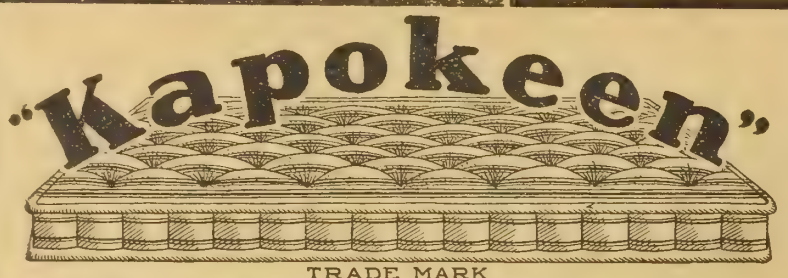
"Kapokeen"



TRADE MARK

The Mattress of Quality

In introducing our Kapokeen Mattress to the readers of The Cultivator, we are taking the first steps toward establishing a National reputation and market for an article, which, on account of its many advantages, has gained a pre-eminent position in its own vicinity.

"Kapokeen" is made from the Kapok or silk floss obtained from the bean of the Eriodendren tree, grown on the island of Java. It is prepared by our own patented process, which removes every particle of seed and preserves in full the resiliency of the natural fibre.

The mattress is made in our own factory where every precaution has been taken to insure absolutely hygienic conditions, by skilled workmen using only the best quality of materials throughout.

NOTE THESE POINTS.

Kapokeen can be "made over" in exactly the same manner as hair.

Kapokeen is sun dried, sun cured, and free from chemicals or other foreign substances.

Kapokeen, no matter how long it has been in use, by being placed for two hours in the sun, will expand and become as resilient as a new mattress.

Price *No. 1 Kapokeen Mattress, 4-4 size, 5 1-2 inch box, Imperial edge satin ticking* **$15.00**

Three-Quarter Size, $12.50 *Single,$10.50*

Kapokeen Mattreses are made only by

John Breuner Co.

A postal will bring you a little booklet describing this mattress

Angle Lamp

The Light That Never Fails

Thousands in use all over the country. A good light is the greatest pleasure and the first necessity of every home.

The only lamp on the market that is sold under an absolute guarantee.

Remember, the light from Kerosene is the light science has agreed upon as being the purest and best, because it is soft and mellow and restful to the eyes.

Here are a few of The Angle Lamp Merits:

NO UNDER SHADOW. NO SMOKE, NO ODOR, LITTLE HEAT.

GREAT ECONOMY—COST LESS TO BURN than an ordinary lamp. As easy to operate as gas or electricity, and better than either. ABSOLUTELY SAFE under all conditions. Lighted and extinguished like gas. Burned HIGH or LOW like GAS without a trace of odor. And a BRILLIANT, soft, steady, shadowless light—but this you will have to see to appreciate.

The lamp as shown in cut burns 22 hours on 3 quarts of oil.

messieurs. I shall not weep." But her voice broke nevertheless, for at the last words Jack was standing up with the bag in his hands. He dropped it heavily over the boat's side and it slid from sight in a moment.

It was quite dark when we beached the boat and turned up the narrow little paved way that led to the cottage; but not too dark to see even a darker shadow rise from the step, stretch to the very tip of its inky tail and walk majestically down to meet us.

"Mere de Dieu!" cried the old woman, crossing herself. "We have drowned her, and behold, she resurrects herself!"

"Eight times she has been lost, given away, killed off," broke in Jack, sadly. "Eight times. Mere Barbizon, it is plain to see that Grisette is now entering upon her ninth and last life."

"Mere de Dieu!" chattered the old woman again. "Behold, messieurs, a miracle, is it not? This time assuredly Grisette shall die as Monsieur le bon Dieu wishes," and still crossing herself, she hurried away for the favorite tid-bit.

"What was in the bag?" I asked Jack.

"Stones," he answered, cheerfully.

About the House

Citron.

Regarding the preserving of citron which appeared in this department recently, Mr. C. E. Rumsey of Riverside writes:

"In household department this is replied to—but only partially. It is too much work for housekeepers to put up dried citron, but it makes delicious preserves. Cut it in small slices—leaving skin on each slice and soak it a while in hot water to take the bitterness out—then cook in syrup pound for pound and you have a most delicious highly flavored preserve. Any ginger or lemon changes the flavor. If the soaking is just enough to take out the bitter and leave all the flavor that you get when you scratch the skin of fresh fruit, it will be something new to most people. I think the highest flavor is before the fruit turns too yellow, but it is good even then. The bitterness varies with its age, and it is best to experiment about soaking. Do not cut slices very thick.

If you want halves like dried citron, it must be cooked in five per cent syrup, then ten per cent, then stronger, or it will not "cook in." If citron for cake is wanted, take some of these slices out of syrup and dry a little. It is as good as that bought, and far easier to prepare."

A COUNTRY CLUB.

Some time ago I chanced to be a guest at a club meeting which was called a domestic science demonstration. Every woman had work of some kind, embroidery or fine stitchery, buttonholes, or darning, and all freely compared notes as to methods and prices. Towards five o'clock three of the women slipped away and prepared the supper. Every one had contributed something, so the three did not have so very much to do to get it on the table in hot and appetizing form. I remember we had chicken pie, mashed potatoes and coffee, besides relishes of various kinds. Each woman present afterward answered a sort of club roll call by giving something from her experience

Don't Wear a Truss

After Thirty Years Experience I Have Made A New Discovery For Men, Women or Children That Cures Rupture.

Costs You Nothing To Try It.

If you have tried most everything else, come to me. Where others fail is where I have my greatest success. Send attached coupon today and I will send you free my book on Rupture and its cure, showing my new discovery and giving you prices and names of many people who have tried it and were cured. It is instant relief when all others fail. Remember I use no salves, no harness, no lies.

I send on trial to prove what I say is true. You are the judge and once having seen my book and read it you will be as enthusiastic as my hundreds of patients whose letters you can also read. Fill out free coupon below and mail today. It's well worth your time whether you try my discovery or not.

as housekeeper, some easier way of doing a little daily task, some prized recipe, some "trick of the trade" in short. No one was keeping a note-book although it seemed to me that a little bride who was a member would have gladly done so from her frantic efforts to get exactly all the directions of the older housewives.

At half past six the women went home. I asked how their husbands liked this arrangement and they said they bribed them to good-nature when forced to eat a cold supper occasionally by giving them a big club dinner every three months. Several of these women drove three and five miles to attend. They all said the club meant a great deal to them and they wondered why they had gone so long with no outing except to church and occasionally to a neighbor's. Now there was always something to look forward to and the expectation stimulated them so it was a pleasure to work a little harder and so make time for the fortnightly holiday.

I wish I could make the pleasures of that afternoon vivid enough to other women so that they would arrange to have these joys of club life, of companionship, exchange of ideas, of mutual improvement and individual pleasure, too. It is such a simple matter to start such a club that I wish those of the Cultivator readers who do not have something of the sort already would ask half a dozen of the congenial women who live within a few miles of each other to meet together some afternoon and try it. You will find the easiest thing about it is to enlarge the membership later on.—C. S. M.

BUTCHERING TIME RECIPES.

Mrs. J. R. King of Gridley, has heretofore furnished some excellent hints to Cultivator readers, and now sends the following Butchering Time Hints:

Brains.

For a breakfast dish, add one cup of chopped, parboiled brains to a four-egg omelet; or to scrambled eggs; or to creamed potatoes.

Mock Oysters.

Take parboiled brains, cut in small pieces, dip in egg and cracker dust and fry till brown. Serve with sliced lemons.

Horseradish Sauce.

One-half cup of thick sour cream mixed thoroughly with one dessert spoonful of evaporated horseradish. Cover and let stand ten minutes, then add a tablespoonful of vinegar.

Meat Jelly.

Not every country cook realizes that the liquor from boiled pigs feet may be strained and set away for use in the place of gelatine in vegetable aspics. Take the desired quantity of the jelly when it is set and add seasoning. Heat and pour into small moulds decorated with slices of hard boiled egg or little red radishes. Let stand over night, and then turn out on lettuce leaves. Makes a decorative dish for the Sunday dinner table.

Crackling Cornbread.

Sift one teaspoonful of soda with half cup of flour into one pint sour milk. Add salt to taste and one cup of finely chopped cracklings, with sufficient cornmeal to make a thin batter. Bake in well greased gem pans, or as thin pone.

Dutch Apple Cake.

When moulding the bread for the pans, reserve a pint of the light dough. Add half cup of sugar, lard size of egg, and knead well. Spread in well greased pan in a flat thin loaf about one and a half inches thick. Cover the top with pared slices of tart cooking apples—be sure they are a good baking kind. Sprinkle generously with sugar, cinnamon and dots of butter. Let rise and bake carefully as the sugar is likely to cause the loaf to burn. Serve cold with pork chops and coffee for a fine breakfast, or hot with a bowl of whipped cream for a hearty dinner dessert.

Lye Hominy.

Take one quart of best white flint corn. This will make over two quarts of hominy. Put on to boil with plenty of water to which is added two heaping tablespoonfuls of powdered lye. Let boil till the dark flake at the base of each kernel is eaten loose, and the corn is somewhat softened. Be sure this part of the process is well done. Then wash in running water till the dark flakes all float off leaving the corn clean. This requires several barrels of water. Then boil in several waters until the lye is all washed out of the corn, and so continue until the hominy is thoroughly cooked. This will keep some time in cool weather, and is liked nicely browned in bacon drippings.—Mrs. King.

WHAT THE EMMANUEL MOVEMENT REALLY IS.

"What is this idea that has aroused a storm of opposition and approval from one end of the country to the other?" says Woman's Home Companion for March, and then proceeds to answer its own question completely and effectively. The movement, started by Doctor Worcester in Emmanuel Church, Boston, has spread, until now it embraces seventy-five churches. It is brought out plainly in this article that, while the mind's influence over the body was demonstrated centuries ago, the Emmanuel Movement is an absolute departure, because it is a combination of religion and medicine—the physician and the minister working hand in hand to relieve the sufferings of mankind. Every step of the movement has been undertaken under the auspices of the physician. Its great value to the church is brought out clearly. In this March issue, Dr. William B. Parker says, in part:

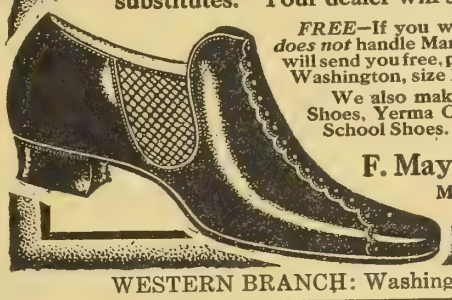
"Its significance to the church is hard to overestimate. It means turning the minds of men back to the church for practical help and succor. To the teacher, the student, the reader, the thinker, it means having a new topic added to his interests, a new region opened to development. It is comparable to the popular discovery of psychology twenty years ago, when that became the most interesting subject of reading in the world. It means clearing away mist and confusion from a subject of great importance and letting in new light upon the working of our minds. It means strengthening each man's confidence in his ability to help himself and his fellows. To the clergyman it has given an effective argument for the power of the spirit, the efficacy of prayer and the presence of God. To the medical profession it has done perhaps the greatest service in checking, if not curing, the materialism which was so general in its ranks."

Mayer

Martha Washington Comfort Shoes

You will never know what genuine foot comfort is until you wear Martha Washington Comfort Shoes. They relieve tired and aching feet and make walking a pleasure. They fit like a glove and feel as easy as a stocking. No bother about buttons or laces—they just slip on and off at will. The elastic at the sides "gives" with every movement of the foot, insuring free action and a perfect fit. *Absolute comfort guaranteed.*

Beware of imitations. Only the genuine have the name Martha Washington and Mayer Trade Mark stamped on the sole. Refuse substitutes. Your dealer will supply you; if not, write to us.



FREE—If you will send us the name of a dealer who *does not* handle Martha Washington Comfort Shoes, we will send you free, postpaid, a beautiful picture of Martha Washington, size 15x20.

We also make Honorbilt Shoes, Leading Lady Shoes, Yerma Cushion Shoes and Special Merit School Shoes.

Hay.

1909 crop contracted for at 10@11½.

Scott & Magner say business locally in San Francisco is excellent and picking up. The demand for hay is good and arrivals are taken care of just as fast as they come in. The interior demand is not quite as strong as it has been, owing to the increase in the pasturage as the good weather has improved the green food.

A careful canvass of the situation seems to indicate that the market will not reach any higher point, and that there is a sufficient demand on hand to carry us through until the new crop begins to come in. All grades of hay sell apparently equally well, with the exception of the poorer grades of alfalfa and stock hay.

Alfalfa continues to sell readily, but there is an apparent weakness in the alfalfa market, and a feeling that the demand will drop off now very suddenly, as the users are able to take the green grass instead.

The general range of prices on today's market is as follows:

Choice wheat hay per ton	23.00@26.00
No 1 wheat or wheat & oat	21.00@24.00
No 2 wheat or wheat & oat	17.00@20.00
Choice tame oat	22.00@24.00

Citrus Market

LOS ANGELES, March 17, 1909.

Oranges are going forward rapidly but as noted last week at prices not as satisfactory as a few weeks since. No promise of immediate betterment appears, though it is hoped that as soon as warmer weather comes in the East and push carts can get out that improvement may be made.

Lemons are moving forward and at satisfactory prices.

Shipments.

Total shipment to date 12,144 cars of which 10,391 cars were oranges and 1,753 lemons.

NEW YORK, March 15.—Fifty-one carloads of oranges and three carloads of lemons sold. Navels in good demand when of good quality, but ordinary stock is dull. Market easier and lower.

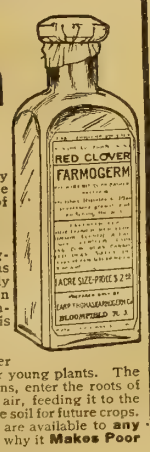
For Larger Crops and Richer Soil at Lowest Cost Fertilize With

Farmogerm



High-Bred Nitrogen Gathering Bacteria

Let us show you the **sure** way to supply your soil with enough nitrates to produce several bumper crops at the low cost of $2.00 an acre, and with practically

No Extra Work

You can use Farmogerm with any legume—Alfalfa, all the Clovers, all Peas and Beans, etc. It is put up in specially sealed bottles, **guaranteed** to contain enough bacteria of strong vitality to inoculate the seed or soil specified. It is

Ready For Use

when you get it. Just mix with water and moisten seed or spray seed bed or young plants. The bacteria multiply rapidly by the millions, enter the roots of the plants, draw nitrogen from the air, feeding it to the growing crop or storing still more in the soil for future crops. All the nitrates they store in the soil are available to **any kind** of crop you plant next. That's why it **Makes Poor Soil, Good Soil.**

Send for proofs or prove it yourself by making a

Box Test For 10c

When you **know** what Farmogerm will do, you will use lots of it. That's why we offer a trial for 10 cents—enough to make a test in boxes in your house before planting season. In regular sizes, $2.00 an acre: Garden Size, 50 cents.

Write For Free Book No. 37. which gives full information. Or send 10 cents for trial size, or more for larger amount, mentioning crop you want it for. For sale by leading seed houses.

A HINT WORTH HEEDING.

Many of our readers know, by reputation at least, Mr. Geo. T. Powell of Ghent, N. Y., who is President of the Agricultural Experts Association. It appears that in 1907 Mr. Powell made a practical test of Farmogerm, the nitrogen gathering bacteria culture, that has attracted much attention of late. In 1908 Mr. Powell reported his experience as follows:

"I planted Red Clover last year, treated with Farmogerm, and it was greatly benefited. This year I planted corn on the same land, and on adjoining land. The corn on the land where the inoculated clover was grown was much better and matured earlier."

All reports show that. It is used by simply mixing with water and moistening seed, spraying over soil or young plants. It comes in a specially sealed bottle and keeps for months. An instructive book about soil inoculation and Farmogerm particularly may be had free by writing to the Earp-Thomas Farmogerm Co., Bloomfield, N. J., and requesting a copy of their free Book No. 37.

DEMONSTRATION TRAIN—INSTITUTE ON WHEELS.

(Continued from Page 314.)

hall or church, as was the case in Pomona, and a regular farmers institute held. Either Prof. Clarke or Commissioner Jeffrey presided. Mr. Graham of the railroad company usually presented the matter of the institute train, why the railroad people considered it wise to lend this encouragement to the farmer. He showed that the farmer's interest was the interest of the railroad in the production of large crops.

Pres. Benj. Ide Wheeler of the State University usually followed, and his address was always genial and one of the most interesting of the session.

Prof. Babcock spoke on methods of combating plant diseases, laying special stress on the advisability of breeding resistant and immune varieties instead of making direct attack on the disease itself. This method has been followed with the melon blight and the walnut blight.

Prof. Loughridge spoke of the needs of California soils, from which we will quote in a later Cultivator, as we will of the talk of Dr. Haring on Sanitary and Certified Milk. Commissioner Jeffrey and Mr. Ehrhorn spoke of the work accomplished by the State Commission and of the necessity of ever increasing watchfulness to prevent the entrance of new pests to our state.

The most regrettable feature of the trip has been the lack of attendance in some of the towns visited. The perfect weather and the necessity of cover crops being turned under, together with other duties which come at this time of the year have made life so strenuous for the farmers that many could not break away from the plow to visit the train. Besides, many have not known of it, owing to the short time allowed for the announcement after the dates were definitely fixed. But with it all there will be a great uplift to the farmers who have been able to visit the cars and doubtless there will be greatly increased production as a result of this service given to the farmers of California by the big corporation, the University and the Commission.

SHAKE-SHAKE-SHAKE-No Stopping It

YOU can buy any one of many kinds of common "bucket bowl" cream separators and be positively certain the "bucket bowl" will eventually shake itself to pieces. Or you can buy a Sharples Tubular Cream Separator and be positively certain **it will never shake.**

Here's the Reason:

COMMON "bucket bowl" separators have a heavy "bucket bowl" set heavy end up on top of a spindle which is held up by several bearings. The weight is **above** the bearings. Such bowls constantly try to tip sidewise. If they did not want to tip, why have bearings to hold them up? This tipping wears the bearings, allows the bowl to shake and eventually wracks the machine, causing expensive repairs or the purchase of a new machine. There is no way to prevent the "shakes" in common "bucket bowl" machines.

YOU can surely avoid a shaking separator by getting a Sharples 1909 Tubular "A". Sharples Separators are entirely different from all others. They have light bowls, hung **below** a single frictionless ball bearing. Being hung naturally, with their weight **below** the bearing, **Sharples bowls can not and do not tip sidewise, shake or vibrate.**

SHARPLES bowls run as smoothly after 20 years use as when new. Tubular "A" bowls weigh just about half as much as common "bucket bowls," yet wear many times as long.

SHARPLES Separators are the only kind with suspended bowls fed through the bottom—the only kind that do not get the "shakes." **Our patents prevent others from making them.**

SHARPLES Separators are made in the world's biggest, best equipped cream separator works. We have additional factoriesi n Canada and Germany. 1908 sales were far ahead of 1907—way beyond any other make, if not all other makes combined. Write today for Catalog 260.

Sharples Separators are most easily and perfectly oiled. Simply pour a spoonful of oil right down among the enclosed, dust proof gears once a week. The lower gear wheel, when in motion, sprays the oil over the gears and the single, frictionless ball bearing supporting the bowl. Most convenient, insures perfect oiling with least attention, and adds wonderfully to the easier running and greater durability of Sharples Separators as compared to others.

The Irrigation of Our Great Valleys

Some Observations on the Water Supply of the Sacramento and San Joaquin Valleys.

Written by F. W. ROEDING of Irrigation Investigations, U. S. Dept. of Agriculture and Read at the Davis Institute.

THE great central plains of California, otherwise known as the Sacramento and San Joaquin valleys, with a length of about 350 miles and an average breadth of 45 miles, contain 10,000,000 acres of deep alluvial soil, with a climate unsurpassed in its adaptibility to diversified agriculture. It is here, unquestionably, that the state will see its greatest development. That progress has been slow as compared with other sections of the state, may be attributed to several causes, the principal one dating back to the days of the Mexican Grants, which were the forerunners of the large grain ranches, whose vast areas devoted to the growing of wheat have been the subject of authors and poets and the marvel of visitors from all sections. These grants, numbering fifty-four and containing about 1,700,000 acres, many of which are still undivided, became the nucleus of grain farming on a gigantic scale. The ownership of such immense areas by few individuals is recognized as a detriment to development and is primarily the cause of the lack of progress in bringing about the growing of more valuable crops throughout this region and their more rapid settlement.

Although in isolated places, orchards, vineyards and alfalfa could be grown without the aid of irrigation, it was early recognized that the artificial application of water to the soil throughout the hot, rainless summers was absolutely necessary in producing crops outside of grain. The cost of securing an irrigation system to individuals owning these large ranches was prohibitive, while with wheat at a good price and a virgin soil, they were able to make good return on their investments. That the continuous cropping of the soil to the same plant would gradually exhaust its fertility was never considered.

The Awakening.

The San Joaquin valley first felt the effects of this exhaustive method of farming, due to lighter soils and a smaller rainfall than its northern neighbor, and we therefore find irrigated agriculture well established and rapidly developing in this region, while grain farming, although practised to a large extent, has seen its best days. In the Sacramento valley, however, the cereals are still produced extensively, but the poor price and the decrease in crops are generally turning the attention of the grain farmer to his more prosperous neighbor, whose land is under ditch. That grain farming will always be a feature of both valleys cannot be doubted, but it will be on smaller areas than heretofore, and under more scientific methods, both of rotation and seed selection—the former in connection with summer crops such as sugar beets under irrigation.

It is needless to state the increase in value of lands under irrigation, or the returns which are to be secured from these; the facts are too well known. The question then arises: Can sufficient water be secured from the streams draining this region to irrigate it? In considering this question it is necessary to divide the two great valleys and consider each separately.

The San Joaquin Valley.

This valley, whose northern boundary is considered on a line passing east and west through Lodi, contains 70 per cent of the land included in the boundaries of the great central plains. Of this, approximately one and a quarter million acres is swamp and overflow land, a large proportion of which has been reclaimed. This land can then be eliminated from our consideration, as here drainage alone is the feature of its reclamation. There are also about one and a quarter million acres which are and can be irrigated. Of this area about one-third lies west of the trough of the Valley, and there are no streams in the Coast Range whose flow could be relied upon for irrigation, even during the rainy season with complete storage. The development of this region will therefore depend largely on pumping, except that portion close to the San Joaquin river, which is at present largely under ditches. That pumping is feasible is evidenced by several plants on the higher lands.

Water for gravity irrigation comes therefore entirely from the Sierras, and the average annual flow of all the streams may be placed in round numbers at 15,000 cubic feet per second. Placing the duty at one cubic foot per second to each 160 acres, and not considering the present status of our water laws or litigations which would arise from any subsequent diversions from these streams, this amount of flow would be sufficient to irrigate about two and one-half million acres, or in other words, double the present area under irrigation. This acreage could also be augmented by the prevention of waste through seepage and evaporation and better methods of distribution, but as the two former would mean a tremendous outlay for ditch linings and piping, they cannot now be considered, although eventually it may pay to follow the system adopted in Southern California. Pumping for irrigation is already largely used throughout the upper portion of the Valley and aside from the increased cost of installation and maintenance is entirely successful.

The Sacramento Valley.

Here we find conditions far more favorable for gravity ditches than in the San Joaquin valley. With an area of about 3,000,000 acres, one-fourth of which is swamp land, we have streams flowing throughout the year from the Coast Range as well as from the Sierras. Stony, Cache and Putah creeks with proper storage can take care of the greater part of the land west of the Sacramento River. We also find that the tributary watershed has an average flow of about 35,000 second feet, or sufficient to irrigate the entire valley without particularly affecting navigation on the Sacramento River. It is therefore to be expected that when the benefits of irrigated agriculture are more fully realized, the Sacramento valley will awake to its opportunities and become a community of small farmers with an endless variety of high grade crops.

In conclusion, there is nothing to prevent the early settlement of all the good lands throughout the great central plains, and that this settlement is going on and increasing is largely due to the energy and enterprise of the various communities interested.

With the Citrus Growers

CITRUS ORCHARD WORK IN ARIZONA.

The following is written by J. Elliot Coit of the Arizona Experiment Station:

Cultivation.

Clean and thorough cultivation in the summer and a leguminous cover crop during the winter, is unquestionably the best management for Arizona orange groves. Thorough tillage not only puts the soil into condition to take irrigating water more readily, but checks evaporation from the soil surface. Cultivation also secures aeration of the soil, with consequent access of oxygen to plant roots; and it promotes the action of those soil bacteria which render plant food available. But clean culture the whole year round as practiced by some is not wise, for, especially in the hot, dry climate of the Southwest, the humus is by that means oxidized and exhausted from the soil.

One of the chief troubles with Arizona soils is their deficiency in humus and it is necessary that we improve the humus content of our soils if we wish an orange grove to be permanently successful. This can best be done by growing some leguminous cover crop, such as sour clover, during the winter months and turning it under in the spring. The seed of this clover may be secured at little cost. It should be broadcasted in late September or early October at the rate of about fifty pounds of seed to the acre. It will make some growth in the fall and remain pretty much at a standstill during the coldest weather. With the first warm days of spring it makes an enormous growth and produces from fifteen to twenty-five tons of green vegetable matter to the acre, which when turned under decays and gradually assumes the character of humus. A note of warning should be given here. In sowing sour clover seed which has been bought at flouring mills, one is liable to get seed which contains some Johnson grass, and a close watch should be kept during the summer for this and other weeds scattered with the sour clover. Johnson grass should be kept out by pulling the seedlings before they are permanently rooted.

Some growers use two cover crops a year, one of sour clover in the winter, and one of grass and weeds during July and August. This plan is a good one so long as the summer cover crop is allowed to occupy the ground only during the season of summer rains and is thoroughly disked in by the middle of September. A summer cover of cow peas would be even better than one of grass, for they would add to the soil a large quantity of that much needed element, nitrogen. This may be added directly to the soil by the application of nitrate of soda or sulphate of ammonia, but since these fertilizers are very expensive, the growing of leguminous cover crops which supply both humus and nitrogen is to be preferred.

Irrigation.

It is of course impossible to maintain an orange grove anywhere in this arid country without a dependable supply of irrigating water. The orange grower who derives his water from a pumping plant has a decided advantage over the man who is dependent upon the ordinary canal. The orange grove which is sandwiched in between alfalfa ranches must take its water in a large head for a few hours only. This necessitates a hurried irrigation which gives no time for deep soaking.

For best results, the water should be conducted in a head ditch or flume along the upper side of the grove and should be allowed to flow in very small streams into deep furrows along the tree rows. Sometimes several days may be required for the water to reach the lower ends of the rows. This method allows the water time to soak in deeply and reach all the lower roots, encouraging their growth. If these furrows are always run straight down the rows in the same way, there is danger that the water continually rising and evaporating about the bases of the trees may in time cause at these points a concentration of alkali sufficient to injure or destroy a portion of the root systems of the trees. This very undesirable condition may be remedied by throwing up borders on each side of the tree rows and thoroughly flooding them. Water sufficient to thoroughly soak the ground and redistribute the salts should be applied at this time. It should be borne in mind that the amount of salts contained in the ordinary citrus soils of this region is not sufficient to injure the trees so long as it is distributed throughout the soil. It is only when, by poor methods of irrigation, soluble salts are concentrated in certain parts of the soil that they become a menace.

The check system is more thorough than the furrow system and effectually prevents the rise of alkali, but it entails more labor and there is more danger that the water will come in contact with the bark of the trunk, causing gum disease. It is much better to give the grove a thorough and deep soaking once in three weeks than to run the water hurriedly through shallow furrows every eight days, as is so often done in Salt River valley.

Pruning.

Orange trees as a rule require much less pruning than stone fruits, but this does not necessarily mean that such pruning as must be done is unimportant or may be entrusted to inexperienced or careless hands. The most painstaking pruning should be done at the time of planting. At this time the tree should be severely headed back to about twenty inches. This will force it to branch out low and form its main framework near the ground.

In former years the trees were headed some five or six feet from the ground, leaving the trunk bare. It has been found much more desirable to head low and prune so that the branches may sweep the ground. This protects the trunk from the rays of the sun and also to some extent from cold. The fruit is much more easily harvested from low headed trees and the branches shade and mulch the soil.

After the young tree is once well headed and shaped, it is only necessary to do light annual pruning, when all dead wood should be removed and the inside branches somewhat thinned

out. A thick canopy of leaves should be maintained, for it is the common observation in Arizona groves that the most fancy fruit grows in the shade. The sun is so intensely hot that there is a tendency for those oranges which are fully exposed to bake and blister.

Often rapid growing sprouts will break out from the trunk and push their way up through the top of the tree. These should not all be removed but some should be left to renew the top of the tree, the older and weaker branches being taken out from time to time. The main idea in orange pruning should be slow but systematic renewal.

If the trees have been slightly injured by the cold, they should be left alone until the injured twigs have become dry, when they may be broken out. Small trees are much more susceptible to cold than large ones, and in case they are badly frozen and the trunks killed they should be cut off near the ground, thus promoting the growth of new sprouts of which all but the strongest should be cut away. If this rises from the root it should be budded when it attains proper size.

HAWAIIAN PINES IN THE UNITED STATES.

Hawaiian pineapple growers have arrived at an agreement that includes a most important plan for a comprehensive effort to increase the consumption of canned pines in the United States.

This plan is one of the results of the combination of the pineapple growers into a marketing organization somewhat after the lines of the Sugar Factory Company, which has been accomplished, all but the actual execution of the papers.

It has been apparent for some time that the production of pineapples in these islands was increasing much faster than the market for them was, and that sooner or later a condition would be reached where there would be an over-production with the consequent demoralization of the market and loss to the producers. The panic in the United States a year ago accentuated this fact and brought home to the growers that something must be done to increase the market or there would be a smash in the business of production, just as there has been in the past at some time, in almost every line of California fruits. It was clear that 80,000,000 of people could furnish a market for a very much larger production of pineapples than has as yet been reached or is likely to be reached for some time to come. But it was also clear that they would not furnish that market unless something was done to increase the use of canned pineapples among them. Some work of this kind has been done by some of the pineapple canneries, but it has not been comprehensive in its scope, no one concern, naturally, feeling like spending its money in a general campaign of education out of which its competitors were likely to get as much benefit as itself. It was seen that combination to this end of advertising and education was the only equitable and efficient way, and finally combination to that end has been secured.

A booklet is to be prepared showing in how many different ways canned pineapple can be used to make appetizing dishes, ices and drinks. These are to be circulated largely through the wholesale and retail dealers who handle Hawaiian canned pineapples. It is expected to prove a means by which they can increase their sales.

In addition to all these, demonstrators are to be sent through the cities and principal towns to demonstrate the methods of using canned pineapples in culinary operations and as a table fruit.

The agreement to carry on this work is at present for a year, and $50,000 has been appropriated for that purpose. To raise this amount the growers have agreed to contribute in proportion to their pack, the total pro rata per case being 13 cents, of which 2 cents per case has already been called for.—Fruitman's Guide .

THE ORANGE.

Where did the orange originate? De Candolle says the Burmese peninsula and Southern China was probably its original home. From there it reached India, and later, Western Asia and Europe. Arabia had them in the twelfth century and the tree followed the tide of Mohammedan conquest through Africa and Spain. It was cultivated in Italy in the sixteenth century. Spanish colonists brought it to the West Indies and Spanish buccaneers planted it in Florida, though the wild or bitter orange has been known here ever since Florida history began, and there are many who regarded it as indigenous to the peninsula. The present extensive list of budded varieties is the result of careful work on the part of botanists and nurserymen who have probably improved the flavor at the expense of its frost resisting qualities.—Florida Produce News.

Cannery employees at Gridley observed their annual spring picnic. This has become an important feature every year in that community.

Deciduous Fruit Culture

By J. W. Mills

CORE ROT OF THE JONATHAN APPLE.

"A YEAR ago specimens of Idaho Jonathans were received at the Colorado Agricultural College for inspection," writes W. Paddock. To all outward appearances these apples were sound, but when cut in two there were varying amounts of discolored tissue, from slight discolorations to those specimens where nearly the entire apple was involved. To all appearances the specimens had been slightly frozen. This year we have received complaints of a similar nature from various sources in regard to this variety.

It seems that this trouble has been noted in Idaho for several years, and in Bulletin No. 54, of the Idaho Experiment Station, by Professor Judson, issued in 1906, we find the following:

'Much of the complaint recently lodged against the Jonathan because of rotting at the core is doubtless attributed to late picking. Unless this trouble is corrected, the sale of this valuable variety is sure to be hurt. The purchaser is completely deceived by the perfect appearance of the fruit, not a sign of decay being visible until it is cut open, when the flesh for some distance about the core is discovered to be brown, radiating in narrow rays toward the skin, which, however, it seldom reaches. It is worse than a worm hole, for that can be cut out. A box containing even a few of this sort of apples makes the consumer distrustful of the variety, while half or more sickens even the most enthusiastic friend of 'Brother Jonathan.'

'To get an idea of the effect of early and late picking upon this trouble, I requested Mr. C. C. Eiffe, of Payette, in the fall of 1904, to pick a box a week for several weeks, beginning as soon as the seeds turned, and keep notes on the appearance of the core rot in storage. His results are confirmed by the experience of several growers in that valley, and are not open to serious question. One box was picked September 11th, a second a week later, and a third one morning in October after a heavy frost. In January the September boxes were found to be keeping equally well, the ratio of sound apples to decayed being six to one; whereas the October box showed a precisely inverse ratio—six rotten to one sound. In May, long after the late-gathered apples were gone, a considerable number of the early-gathered still remained juicy and in good condition. There is probably no other winter apple for which prompt picking is so important as the Jonathan.'

The season of 1908 was peculiar, and various causes were responsible for the apples being under size. Because of the small size of the fruit the growers naturally deferred picking as long as possible with the hope of increasing their output of the fancy grade; and in many instances, at least, the apples were eating ripe before they were gathered. Judging from the Idaho experience, it is probable that the trouble with the Colorado Jonathan this year is due to this course. If the apples are picked promptly as soon as in condition, it is likely that this trouble will entirely disappear. At any rate, we are certain that there is no fungus involved and that the condition is one which the growers may readily control. The Jonathan apple is too good a variety and has too good a reputation for us to allow anything to happen to it. We believe that it lies with the growers to correct this fault; and when once their attention has been called to it, there will probably be little complaint of a similar nature in the future."

ON THE GROUNDS OF J. H. ADAMS, COVINA.

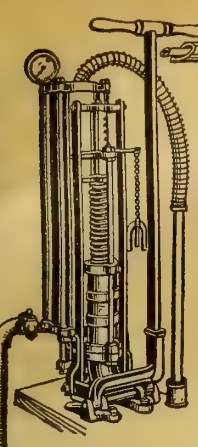
WASTE IN SULPHURING VINES.

Sulphuring of vines is usually sulphur and effort well expended. However we note the following by Prof. F. T. Bioletti as to that work last year, spring of '08:

A great deal of sulphur and labor have been and are being wasted in treating vines for mildew this year, especially in the interior.

A year like this, with a long hot, dry spring and early summer is so unfavorable to the growth and spread of mildew that in many districts there would be done of this disease even if sulphuring were neglected completely.

Throughout the great central val-



This is the Pump

that can be operated continuously at high pressure without the muscle-racking, exhausting, "man killing" exertion required for ordinary pumps. High pressure spraying means more and better fruit—and consequently more money for the grower.

Bean Magic Spray Pumps

are different from other pumps. They run smoothly and easily without clogging, and one man keeps up high pressure for two lines of hose. And they **save one-third the labor.** The Bean patent spring does it. The operator does half the work at each stroke of the handle, and works against but half the pressure indicated on the gauge. A trial quickly removes all doubt.

Our illustrated catalog No. 21 describes ten sizes of handpumps, and contains much valuable spray information, and formulas. Catalog No. 18 describes Power Sprayers. Both books sent free. Write for our special offer; state number of acres and kind of fruit.

ley, except where summer irrigation is practiced or where the vines are growing along irrigating ditches or in the shade of trees or buildings, one sulphuring should be sufficient to control the mildew perfectly this season, and in many vineyards it would be quite safe to omit sulphuring this year.

Much sulphuring is being done owing to a mistaken idea of what mildew is. Vines with curled, yellowish leaves or poor growth may be suffering from drouth, sunburn, wind, vine hoppers, little leaf, and sulphuring will be quite thrown away on them. Go into the lowest shadiest part of your vineyard, where the vines are growing vigorously and examine the lower parts of the new canes. If any mildew is present now it will be there. If none is there the rest of your vineyard is safe so long as this hot, dry weather continues.

Another way in which sulphur is

AN IMPERIAL VALLEY THREE YEAR OLD TREE.

being wasted is by the use of cans and sacks for applying the sulphur. This will be made clear by the record of two vineyards which I have.

Vineyard A was sulphured by shaking the sulphur out of cloth bags. One sack of sulphur (100 pounds was used to 7½ acres. The cost of sulphur was $26 for 100 acres and the work was badly done.

Vineyard B was sulphured with a good machine, and only one-quarter sack was used to 7½ acres, costing $6.50 for 100 acres. No mildew so far has appeared in either of the vineyards.

BORDEAUX AND EAU CELESTE.

These formulas are given often and as often called for again, so we reprint. This is the formula recommended by the State Horticultural Commissioner:

Bordeaux.

Copper sulphate (blue stone) 8 pounds.
Quicklime ..... 10 pounds.
Water ..... 50 gallons.

Dissolve the copper sulphate (blue stone) in a barrel containing ten or twelve gallons of water. Slake the quicklime and thin it to a creamy whitewash. Pour the whitewash very slowly through a wire screen into the copper solution. Stir the mixture thoroughly and add enough water to make fifty gallons in all. Stir occasionally while applying as a spray to the trees.

In the preparation of the Bordeaux mixture it is necessary that the ingredients should be mixed in a wooden vessel. If an iron one is used the copper will go to the iron and the effect of the spray is largely neutralized. Apply the wash cold and as soon after it is prepared as possible. Never allow it to stand over night.

This is a remedy for curl leaf of peach, shot-hole, fungus, peach blight, pear and apple scab.

Eau Celeste.

For powdery mildew and rust on roses and other plants:

Sulphate of copper (blue stone) 2 lbs.
Ammonia ..... 3 pints
Water ..... 50 gals.

Dissolve the copper sulphate in a gallon of hot water and add the ammonia, after which the mixture is to be diluted for use.

SMUT EXPLOSIONS.

Gas generated by heat from black oil, a by-product of petroleum, used as a lubricant on bearings, and not smut in wheat, as generally believed, is the sole cause of explosions in threshing machines. The use of lard, castor or china-nut oil eliminates all danger of fire or explosion, no matter how much smut there is in the grain.

That is the theory advanced by Silas Privett of Colfax, Wash., a thresherman of 25 years' experience in the northwest, who has operated 10 years in the Palouse wheat belt, south of Spokane, where 27 machines were destroyed in a single season, a few years ago. Mr. Privett believes he has made a discovery which will result in the saving of thousands of dollars a year to farmers and threshermen in the United States and Canada where smut is prevalent.

Explaining his theory Mr. Privett said that black oil produces explosions in the same manner they are created in a gas or gasoline engine. The heat generated by the bearings of the rapidly revolving machinery, upon which the petroleum product flows constantly while in operation, generates a gas, and when a spark, caused by the passing of a hard substance through the machinery or the striking of the cylinder teeth against the teeth in the concave, comes into contact with this gas, an explosion results. He added:

"I have been studying this problem for years, but said nothing about it until after I had made a thorough investigation. As a result I am more convinced than ever that the majority of these fires, if not all of them, can be directly traced to the use of black oil.

"I began operating a threshing machine when I was 15 years of age and continued in the business for 25 consecutive years, and I do not believe that there is a man today in the country who has threshed any smuttier wheat than I have, yet I have never had an explosion, neither have I ever used anything but castor, lard or china-nut oil.

"I have also noticed that while there have been from 10 to 25 fires every fall in Whitman county, supposed to have originated from smut there are three or four threshing outfits which have threshed through the same kind of grain season after season without any fires. I also know that the men having charge of these machines will not allow anything but castor or lard oil to be used."

Small Fruits and Vegetables

EASY TO GROW ASPARAGUS PLANTS.

ASPARAGUS plants can be easily grown from the seed in one or two years' time. If you are in no hurry this is the best plan, but or course if you wish to get a bed started in a short time, it is better to buy the plants of some seedman or nurseryman, as you can thus save a year or two in time. Plant the seed very early in the spring, the earlier the better, in rows of a foot apart. As the seed is slow to sprout it is a good plan to mix in a few radish seed, as they will come up early and make the row and you can tend and keep the weeds down while you are waiting for the asparagus to come up.

The little asparagus plants are very small at first and you should look carefully in weeding or you will pull them up. As soon as the asparagus shows, take out the radishes or they will crowd it out.

Keep well tended and free from weeds, in fact tend just like you would a bed of onions from seed. The plants grow all summer and can be dug in the fall and stored in the cellar or left in the ground till spring.

Early in the spring take up the plants and set them where they are wanted, first putting the bed in the best of condition. Spade it up very deep and work it up fine. It is a good plan to work in a lot of well-rotted manure to make the soil loose and rich. A tolerably moist place is good, but that is not important. Better choose the place that will be most convenient and fix the ground to suit. You can't make it too rich.

Mark out the rows from two to four feet apart and set the plants two or three to the foot in row. Set about four inches deep just about like you would raspberry plants. Cover all over with dirt. The plants are easy to live and if they are covered with dirt they are almost sure to come well.

Keep well tended the first season like you would potatoes. Hoe or cultivate just as suits you best. In the fall cover all over with manure deep enough so that weeds can not come up through it. If any weeds show through in the spring put on more manure. Keep this up every season and you will have no more trouble with the bed. The asparagus will come through any amount of manure. You can begin cutting the second season and from then on the bed will be better every year for a long time and is a permanent affair.—Southern Cultivator.

SAUERKRAUT.

Sauerkraut is easily made, and the home-made article is much better than that offered by grocers. Slice the cabbage with some one of the various vegetable cutters. Pound down in a jar; a wooden potato masher answers for this work. Sprinkle salt on each layer as you put it in. A heaping tablespoonful of salt will be enough for each gallon after it is pounded down; it should be pounded until it looks watery and well bruised. When the jar is full cover with a cloth and lay a plate or wooden cover on it and press down with a heavy stone or weight of some kind. The brine ought to rise on it in about three days, and if it does not, a little very weak brine should be poured over it. 'Tis well to set it out doors until the fermentation is over, as the odor at that time is strong and to most people very unpleasant. It takes several weeks for it to get fit for use, the time varying in accordance with the temperature at which it is kept. It is best to take off cloth and weight and wash them occasionally, as mould will form on them.

Cultivate the sweet potato land frequently to destroy weeds and grass, and fit the soil for the plants. The first setting of plants should be ready by the middle of the month, and the sooner they are removed from the bed the sooner the second setting will come on. If the plants cannot be set out when large enough, they should be pulled off, the tops sheared, and then heeled in to make room for the next setting.

SEED FROM SMALL POTATOES.

It is probably not a good plan to save seed from the small potatoes year after year. But when the crop is cut short by dry weather the result in potatoes will make a good crop the following year if given any chance. In one dry year we raised no potatoes larger than a walnut and from that down to a marble. We planted this seed the next year and it was much like planting peas. But the crop we raised was the best we have ever grown in the West, the season being a very favorable one. This year we had our seed picked out from the best we had, but these lacked three rows of planting the piece. These three rows were planted with the culls from the bin; at digging time this fall no difference could be noticed either in yield or quality between these rows and the others. There are hills among potatoes that produce a great many little ones and no large ones; the danger lies in selecting small seed when many of this kind are present in the field. The small potato taken from a hill of large ones will grow just as good potatoes as the large ones will. If some weather condition made the whole crop small we should not hesitate to use them for seed.—Nebraska Farm Journal.

UDO.

Udo is scarcely known at all as yet. It is a favorite in Japan. It is a shrub that grows during the summer shoulder high. It is another continuous performance plant like asparagus. When cold weather comes it should be cut down to the ground and a bank of earth one and a half or two feet high pulled over it. Later when the weather comes very cold as in a climate where they have hard freezes to contend with, the earth should be covered with manure or other mulch. This plant grows all winter, and in January the delicate shoots can be cut off and like celery, eaten raw; further, they furnish an exceedingly pleasing dish served very much as asparagus is handled with or without a white sauce. It reminds one of the heart of celery. It has a flavor that is distinctly spicy and seems to please all palates.—Green's Fruit Raising.

Quite extensive plantings of peanuts have been made at Beaumont.

The Ornamental Garden

PLANTING OF FLOWER SEEDS.

IN making the garden bed for outdoor sowing of seed, the amateur can save much time and trouble by understanding clearly just what the principle is.

In the first place, remember that almost all the seeds of our common garden flowers are extremely tiny. To put these minute things into rough earth, full of little clods and stones, is like dropping them into a lot of miniature subterranean caves, where they are neither covered properly nor will they get nourishment. The earth into which they go should be so fine that no amount of crumbling between the fingers will make it any finer. If it can be sieved, that is the best thing to do.

But while the seeds need perfectly powdered earth to do their best, they do not need much of it. A few inches in depth is all that indoor seed boxes ever have. Consequently it is by no means necessary to work over the whole garden bed to make it a good seed bed.

On the other hand, however, as the flowers that come up are to stay where they grow, it is extremely necessary that the entire bed be prepared as it should be to provide the proper nourishment and foothold for the plants after their roots begin to go deeper than the upper seedbed.

Therefore the right way to go about making a bed for seeding down flowers is to remove about half a foot or even a little less of the top soil if it is very rich and black earth. If not, get an equal quantity of earth that is good, pass it through a fine sieve if possible, or else rake it and pick it over till it is perfectly fine. Pile it alongside of the bed.

Then go at the latter. Dig it deep, mixing the upper soil well with the lower. Unless the earth is very rich indeed, put some fine well-rotted manure in and turn it under. Rake it all thoroughly, removing all large stones and hard material, and everything that will prevent the earth from forming a good root bed. After the bed has been thoroughly raked and smoothed, trample it down well until it is packed solid. Then rake again thoroughly, because while you want the earth to be well packed, as rain and weather would pack it in time, you still do not want it hard and solid.

After this second raking, cover evenly with the very fine earth for the reception of the seeds. Most of the flower seeds will not need to be dug under. It will be best to scatter them lightly on the ground and then press them in firmly with a flat board. Scatter fine earth, crumbled between the fingers, over them and the work is done.

HOME GROUNDS.

Every home builder, however poor and humble, owes it to his wife and children that he should supply them with every luxury and comfort within his reasonable ability, says a writer in an Eastern Exchange. Every man can have a garden and some fruits. They are cheap luxuries, and within the easy reach of all, requiring only a small investment and a little labor. These, with a fixed determination to make the pursuit of comfort and happiness his first aim and money making an after consideration. This is according to nature's law and order, and is right and God-ordained.

There are thousands of children even on farms who grow to manhood and womanhood and never know the luxury of plucking and eating fruits, ripe, luscious and fresh from the tree and vine. Is it any wonder that your thoughtless boys are tempted to raid your neighbor's orchard or melon patch? Parents are responsible for the vices of their children in more ways than they usually consider. I may further say that the addition of an orchard to any farm, either small or large, adds another opportunity for practical industry, and a desirable avenue for remunerative occupation with educative and refining influences. Whatever makes home more beautiful, more enticing, is not only a blessing to its occupants, but to all who look upon it. In no calling is the habit of quick and accurate observation of greater importance than in home making, home building; and in no place can the beautiful in nature be so blended as in the use of horticultural environments.

THE BACK YARD.

Give your back yard garden a chance to prove what can be accomplished there. Start in early to plan for the arrangement of the little garden spot, choosing the flowers which seem best adapted to it, and when danger of frosts is over, prepare the ground for the reception of seeds. If the space is large, have it dug for you, though if possible, take the time outdoors and accomplish the work yourself. You will enjoy it, and it will pay you a thousand times in health and strength. Do not try elaborate designs, for it will mean enlarged expense, besides taking more time, and the chances are ten to one that it will disappoint you after all. Instead make the flower arrangements as simple as possible, blending two or three pretty flowers and vines, and giving them plenty of room to grow and spread themselves. This will aid in counterbalancing the disadvantages of shade and poor soil. Give your back yard garden a fair chance, and see if it does not repay all your care of it, by filling your summer days with brightness.

Roses in the front yard may not be a quick money crop but they pay big in keeping alive and developing the love of beauty that God has planted in the heart of every man or woman worthy of the name.

Farmers Union at Pendleton, Oregon, has headquarters at that city and one of the features is a beautifully furnished rest room for the farmers wives when they come to town.

The Schmidt Lithographing Company, carrying an advertisement on another page of the Cultivator, appeals to the growers, packers and shippers of citrus and deciduous fruit, and anything in the way of box labels can be secured from this firm on the most reasonable terms. They will be glad to send you a sample booklet of box labels, which will be mailed free on request. Address them either at their San Francisco Office, 2nd and Bryant St., or Los Angeles Office, Henne Bldg., Mr. H. E. Lenz, Manager.

We take pleasure in recommending them to the readers of the Cultivator.

The following is a report of the

California Mutual Live Stock Insurance Association

of the amount of insurance in force in each county in the state. This is done for the purpose of showing to our policy holders the large amount of insurance we are carrying and the way the insurance is scattered throughout the state. One can readily see that a vast numer of farmers and stockmen are joining this Association, which insures all kind of live stock against death from disease, fire, lightning or accident which may necessitate the death of an animal. The best farmers and stockmen are becoming aware of the fact that they cannot afford to be without insurance where the rate is so low and the insurance furnished at actual cost to the policy holders.

THREE FAMOUS OLD TREES.

There is a tree in Cheapside, London, which may literally be described as the most expensive of its kind on earth.

If $5-gold-pieces filled the entire trunk and $5-bills fluttered in the place of its leaves, it would not buy the ground it occupies, for the land on which it stands is worth $4,500,000 an acre. The tree has stood on the spot for 200 years.

There have been several hard fought law suits over this plot of ground, the fight having been carried even to the House of Lords, but so far, the lawyers have never been able to break through the legal enactments which preserve the tree.

Two great oak trees in the garden at the White House are known as the "Peace Oaks." They were planted, previous to the Civil War by John J. Crittenden and James B. Beck of Kentucky. These men, who were representing the State of Kentucky in the United States Senate, attempted to defer the war by means of a peace conference. Their failure was symbolized by planting two acorns from which grew these carefully guarded trees.

Two small seedling oaks—"Peace Trees," sprouted from acorns, the fruit of the "Peace Oaks," have recently been sent from the botanical gardens in Washington to be planted in one of the public parks in Kentucky.—American Farm World.

FLORAL PROGRESS.

If our grandmothers could come back and study a modern flower garden they would be surprised beyond measure. The change in the size, forms and colors of the common annuals would puzzle and delight them. To see this change you have only to compare an illustrated catalog of 1909 with an old one of 1885.

Floral forms have proved very mobile under the skilful manipulations of the plant breeder, and it is almost possible for him with patient perseverance to produce any desired change in shape, color, and size of plant. What is especially striking is the delicate, and fanciful markings, and mixture of colors, in such families as the phlox, pansy and petunia.

Many flowers once so small as to be of little value have advanced in size and consequent importance. Others considered coarse have been refined. Some without perfume twenty years ago, have acquired that attraction.

The amateur flower lover who undertakes a flower garden has much pleasure and some surprises in store. But just a hint from experience: There is more success and consequent pleasure, with half a dozen varieties of easy culture than with a lot of new and strange plants, which may really need expert care to do well.

HOW THEY GOT THEIR NAMES.

Fuchsias were so called because they were discovered by Leonard Fuchs.

Dahlias were named for Andre Dahl, who brought them from Peru.

The camellia was named from a missionary named Kamel, who brought some magnificent specimens of the flower to France from Japan. He called it the rose of Japan, but his friends changed it in his honor.

Magnolias were so called because Professor Magnol de Montpellier first brought the beautiful tree to France from America and Asia.

Anemones mean trembling with the wind—hence their name.

Lavender received its name because the Romans put the delicate flowers into the water where they washed, to perfume their hands, lavare being the Latin word, to wash.—Farm World.

San Joaquin county is to vote upon a proposition of bonding the county for $1,800,000 for the purpose of building good roads.

Live Stock and Dairy

Dairymen and stockmen are requested to write of their experience. Mrs. Sherman is always willing to answer queries and this, with experience of other workers, will make this department of greater value.

By Mrs. Minna E. Sherman

PIGS ONCE MORE.

THE pigs that are to be retained in the yards for breeders should have light weight, metal tags put into the right ears. It is, also desirable to know them apart. The simplest system of numbering I have been able to devise, is to begin by calling the sows A-B-C-D-E- and so on. When sow A has a litter and it is desirable to save some of them, the tags are stamped to read as follows: A-1-09 for the first one, A-2-09 for the second and so on. This shows at once that this young sow is the daughter of sow A and the first litter of '09. The second litter of pigs are marked, A-21-09. Should there happen to be a third litter, these would be marked A-31-09. The next generation's numbering reads, A1-1-10. That is sow A, sow number 1, daughter No. 1, born in 1910. When the sows are registered the herd book number may appear on the upper side of the same tag. The die and tags of a soft steel are bought and the stamping done at home as the tags are needed. The keeping of the number right in the ears of the stock is really the only way to follow the breeding carefully, for whenever you see any marked goodness or anything undesirable croping out, if the stock is marked it can be increased by line breeding, or it may be bred away from, by a distinct out cross.

Growing Stock.

The young sows should be placed in a field of good alfalfa, to encourage them to grow strong and thrifty rather than to make fat. The brood sows should not be "hog fat" to make good mothers. The pigs intended for dressing for pork are the ones to feed the wastes of the horse and cow mangers, while the milk and kitchen slops are given to the sows, nursing pigs and to the little just weaned ones. The little pigs of thirty pounds or so make good sausages, and a demand for farm made "little pigs" sausages can be readily built up. Crops are grown specially for the pigs to harvest. At least six, two or three acre yards should be fenced up for the pigs. The fences made of hog tight wire fencing, strung on live willow posts, make the pig lots wood producing plots. These willow posts, placed six feet apart and pollarded every third year to six feet in height, will produce a large amount of fire wood cheaply, for they are cut when the size to split only once and this can be done for about a dollar a cord. Half of the lots are sown at once to alfalfa leaving three to handle the pigs during the winter season. When the spring time is in the land, the sows are put on one alfalfa field while the growing stock is put into another. The third alfalfa field is left to cut some hay for their winter feeding. The other three fields are plowed and sown to cereals, or if the season is too late they are sown in part to corn, part to peas and part to pumpkins. Any of these crops can be harvested by the hogs in the fall before they are turned off to the pork barrel.

Winter.

Alfalfa does not stand pig-feeding well in the winter time. No matter how carefully they have rings put into their noses, they trample it to death. The crop best for winter and fall sowing seems to be green peas, and when these tops are fed off, the roots are left to furnish the next summer corn crops with nitrogen. Plant with Indian corn or sorghum; the hogs relish either kind, and soon learn to harvest it for themselves.

The sows that eat their pigs probably do so from want of proper food. I have noticed it rarely happens if a sow is on green feed. It seems to be the result of feverishness rather than of malice at first. This sow however should be turned into the pork department at once and not kept to repeat the same cruelty next season. These old sows make a great quantity of lard and if a fat cow is dressed at the same time, and the beef tallow added to the lard it will make it go much further in cooking. It makes a nicer biscuit than all lard.

Feeding the Sows.

After the sow farrows, give her plenty of water, but no food during the first day. The next day give her bran mixed with skim milk, feeding her the first week on bran, slops and alfalfa, either cut green or on alfalfa hay. After that she may be allowed her liberty and given all the slop she will eat as well as all the green cut stuff or green hay. Sunshine is good for the sow and good for the wee piggies. The sows that have large strong litters should be kept and the others put in the pork string at once.

The old formula should be kept at hand to make them thrifty. Much of the "kidney worm" that affects little pigs will be controlled if the old sow can have free access to the following mixture. Eight pounds of wood ashes, 4 pounds of salt, 1 pound of black antimony, 1 pound of copperas, 1 pound of sulphur, ¼ of a pound of saltpetre, 1 pound of charcoal. This kidney worm is characterized by the young animals coughing and acting as though their hind parts were stiff, and at the end or before death they curl back the lips and turn the noses to one side. When they are very sick catch the little chaps and give them a teaspoonful of copperas water and also add some to the sow's slop.

Litters.

The use of a small foot board is important if the sows are penned up with their little pigs, or they will crush them. We, however, have our sows at large and when they begin to carry litter to make a nest, they are allowed to select their own spot and when they are settled, the light roof boards are put over the portable frame work and the sow has a shelter from the rains with her bed on the clean ground. The trouble with any sort of houses in constant use is to keep them clean. They will grow foul in spite of spraying and white wash. The ground becomes contaminated and if we can keep the sows on ground that is not shut away from the rain and sun except for the brief while that she is using it for a nest, the gain in sanitary cleanliness is great. —M. E. Sherman.

No Discarded or Abandoned Inventions of its Beaten Competitors are used in

THE IMPROVED

UNITED STATES SEPARATORS

THE UNITED STATES SEPARATORS ARE IN A CLASS BY THEMSELVES

The United States use inventions of their own **exclusively.**

The United States do not utilize any type of separator ever developed by their **"Would-be Competitors."**

These **"Would-be Competitors"** claim the earth, but "word claims" do not give them the title.

These **"Would-be Competitors"** claim that Dr. DeLaval was the inventor of "the first practical continuous flow centrifugal Cream Separator," his application being filed "July 31, 1879, Patent issued, No. 247,804, Oct. 4, 1881." This statement is not true as shown by the records in the Patent Office. Messrs. **Houston & Thomson** (who afterward became famous in the electrical line) **were the first** to be awarded a patent on such an apparatus. Application filed Oct. 29, 1877. Patent issued April 5, 1881, No. 239,659.

This Houston & Thomson Separator was also of the "Bevel Gear" type and was for either hand or power, therefore the claim of our **"Would-be Competitors"** on this point is not correct.

"These are the Rock-of-Gibraltar-like facts against which mere "word claims" by **Would-be Competitors** fade away like the mist of night before the rays of the morning sun."

We could enumerate a lot of things these **"Would-be Competitors"** claim, that are not in accordance with the facts or the records, "that fade away like the mists of night before the rays of the morning sun" of truth, but this is sufficient on this point for the present, we think, to convince all thoughtful readers that "word claims" do not have any weight in face of the facts.

These same **"Would-be Competitors"** claim their Separator is the Standard Cream Separator of the World, but they are not entitled to that "word claim," as the records show that the **United States Separator** beat them in the greatest contests ever held by any **National or International Exposition.**

In other advertisements they claim that "99½ per cent, of all expert creamery men, butter manufacturers, and real separator authorities living today use **DeLaval Separators** exclusively for they have learned by experience that the **DeLaval** is the only separator that will save all the cream all the time under all conditions."

Now every reader of intelligence knows that is another "word claim" and is not true, because a very large percentage of the leading breeders, separator authorities, creamerymen and dairymen, use and recommend the **United States Separator** because it proved in the great contest with the **DeLaval** and others, that it excelled everything in fifty (50) consecutive runs lasting over one month on ten different breeds of cows; also in every day use it has maintained its superiority.

Please read the following letter and see for yourselves if this looks as though the "99½ per cent word claim" is correct.

Poughkeepsie, N. Y., May 27, 1908.

In 1899 we introduced farm separators in our cream gathering system. Although we are within six miles of the DeLaval Separator's main works where all of their Separators are made, our patrons, after thorough investigation, preferred and purchased the U S.. Separators. There are about three U. S. Separators to every one of the DeLaval Separators used. Since we have started we have steadily increased our output. We get good prices for our butter, and feel proud of the record.

LaGRANGE CREAMERY,
H. R. HOYT, President.

Just think of it, **Three United States Separators to every one** of the **DeLaval** right under the shadow of their factory. **Why?** Because the United States is superior to all others in every feature of separator practicability. It is **made stronger, runs easier, wears longer, skims closer.**

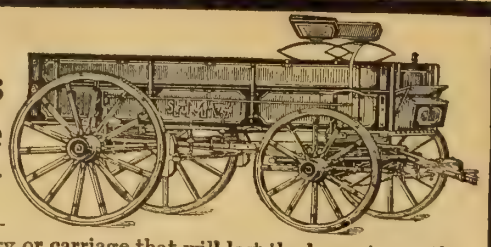
LARGEST VEHICLE FACTORY IN THE WORLD

Studebaker

THE STUDEBAKER PLANT COVERS 101 ACRES

Means Genuine Economy



The first cost of a vehicle or a set of harness is one thing—the yearly cost is another. You want the farm wagon or buggy or carriage that will last the longest, run the easiest, require fewest repairs and, while costing no more in the beginning, will *cost a great deal less in the end.* That's the only *genuine economy.* The Studebaker Bros. Mfg. Co. have built up the largest vehicle and harness business in the world—*solely by saving money* for its customers. If you are looking for a *real* bargain—one that will give you *years* of satisfaction—

See the Studebaker Dealer and let him show you why the *Studebaker lasts* so long, gives such good service, runs so easily and costs so little in the end. You can't afford to run risks—investigate the *Studebaker* line and see for yourself. *If you don't know a Studebaker Dealer, we'll be glad to send you his name.*

FEEDING SUGAR BEET PULP.

IN bulletin No. 90 of the Utah Experiment Station there are some interesting statements regarding the feeding value of beet pulp. It is shown that at the Colorado Station five milk cows were fed 24 pounds of beet pulp for six weeks in addition to hay and grain.. Then for five weeks 12 pounds of sugar beets were substituted for the beet pulp. The average weekly gain on beet pulp was 62 pounds and on sugar beets one-fifth pound. The average weekly milk yield on beet pulp was 131 pounds and on sugar beets 127.4. Over three times as much profit was derived from feeding 24 pounds of beet pulp per day at $1.00 per ton than from feeding 12 pounds of sugar beets at $4.00 per ton. The experiment indicated that with butter at only 20 cents per pound the sugar beet pulp fed in such quantities was worth $2.61 per ton.

At the Michigan Experiment Station beet pulp added to a mixed ration of hay and grain increased the milk flow. The California Experiment Station reports most favorably on pulp as a cow feed. When 20 to 80 pounds of pulp were fed per day there was a saving of four to 14 pounds of hay. The pulp had a most beneficial effect on the milk yield. Most of the cows were decreasing in milk flow at the time the pulp feed began after which there was an increase. A good flow was maintained through the whole period of pulp feeding but there was a considerable decrease after its close. The pulp did not effect the percentage of fat in the milk.

At the Utah Experiment Station the cows there have been fed on sugar beet pulp for some considerable time. The pulp has never yet affected the quality of the milk unfavorably, but has exercised a most healthful effect on the cows and served to increase the milk flow. With these facts in mind it seems that the Utah farmer can do no better than to obtain the sugar beet pulp from the factories, keep a number of dairy cows, and return the fertility already spoken of to the farm.

Experiments conducted in the feeding of the beet pulp to steers, sheep and hogs, have proven no less satisfactory. At the Logan sugar factory Mr. Hans Larsen has fed thousands of sheep and steers for shipment to the Pacific coast. He has found pulp very profitable feed and he values it at $2.50 per ton. His operations have been found successful. He feeds Lucerne pulp regularly twice a day in open yards and only such quantities are given as will be eaten up in a few hours.

The farmers in a great many localities in this state could do no better than to devote their entire attention to this line of farming. A farmer who owns 20 acres of good beet land, 20 acres of good alfalfa land with a few acres of pasture with about 15 to 20 head of cows is an independent man with a constant income of $150 to $200 per month every month of the year. The keeping of the cows on the farm will serve to keep up the fertility of his land and thus he can hand the farm down to his sons in as good condition as far as fertility is concerned as when he took it in its virgin state.

Since the sugar beet factories are pretty well established in various localities of the state we regard the matter of most vital importance that of

returning the sugar beet pulp to the farm and feeding it to dairy cows. We have talked over this matter considerably with farmers during the summer and find they simply have not taken the time to haul it away. If they can be brought to realize that it is worth several times its cost to them then we see no reason why its use could not be more general. It is certainly a well established fact that beet pulp is an excellent substitute for part of the hay and grain for milk cows and we look forward to its more extensive use.—The Deseret Farmer.

COLD CEMENT FLOORS.

Thoughtful, observing men have noted that cold, uncovered cement floors are not a good thing for cows. They have noted, too, that it is about impossible to keep bedding so spread over a cement floor that the cow will not bring her udder in contact with the cement sometimes when lying down. It is for this reason that the plan of covering the cement floor where the cows lie with boards, is so generally recommended.

Mr. L. E. Scott of Stanley, Wis., made the following experiment to determine the difference in temperature of plank and cement floors.

"I once took two basins of water at a temperature of ninety-eight degrees F. and covered top and sides with four thicknesses of cloth to prevent radiation except from the bottom. I put a dairy thermometer in each, placed one upon a plank in a stable and put the other by the side of it upon cement. In fifteen minutes there was a difference of six degrees and in an hour and a quarter the one on the cement was thirteen degrees colder than the one on the plank."

The udder is the seat of an enormous amount of blood circulation. We can easily imagine what the effect will be to bring that udder in contact for an hour, perhaps, with the cold cement. If we check the circulation of blood we are apt to bring on congestion, and garget, and other troubles ensue. Then, besides, it must lessen the flow of milk just in proportion as we check the circulation of the blood. The cow and her right conditions constitute a mighty deep subject. Yet there are plenty of farmers who think that their lack of knowledge is a better guide on this subject than the wisest intelligence.—Hoard's Dairyman.

SOUND AND WELL FORMED.

One of the most gratifying features of the horse business is found in the careful study that has been given to the selection of horses by buyers and patrons. A distinctly higher standard has been established. Many horses of the type and quality that were being sold a few years ago are quickly being rejected now. Many of the unsoundnesses and defects that were passed not long since are now under severe discrimination. Breeders have learned that size is not the only consideration. The very large horse of either sex is likely to prove disappointing as a breeder. Size without quality is certain to prove disastrous. —Prof. Curtis, Iowa.

A good time to buy brood sows is when they are about six months of age. Select sows that are of uniform type, of good breeding, and buy from a reliable breeder.

Feed the brood sow lightly for the first few days after farrowing. Give her all the sweet milk or warm water she will take.

TRADE IN YOUR INFERIOR SEPARATORS

15,000 American users of poor or worn-out separators traded them in last year on account of new

De Laval Cream Separators

and there are doubtless many more owners of such machines who will be glad to know that while such old machines have no actual value the DE LAVAL Company continues to make liberal "trade" allowances for them because of the opportunity such exchanges afford for the most practical illustration possible of the difference between good and poor separators and putting a stop to the sale of others like them in the same neighborhood. Nobody is injured through the re-sale of these old machines as they are simply broken-up and "scrapped" for their old metal value.

Then there are many thousands of DE LAVAL users who should know that they may exchange their out-of-date machines of from 10 to 25 years ago for the much improved, closer skimming, easier running and larger capacity machines of today.

Write in a description of your old machine—name, size and serial number—or see your DE LAVAL agent.

The Satisfied User

Empire Cream Separator Co., Portland, Oregon.
Gentlemen:
I wish to say that I have been using a water separator for the last year. Recently your agent placed an Empire with me for trial and I was soon convinced that my water separator did not get all the butterfat; in fact we ran some of the skim milk from the water separator through the Empire machine, and procured cream. We bought the Empire, and are delighted with it! It is a money-maker! We can make much better butter, and more of it. It is but little trouble to clean. A child of ten years old can run it.
(Signed) MRS. M. MONROE, Vancouver, Wash.
You will be just as well pleased if you will try an Empire.

PARCELS POST.

The visit of Mr. F. C. Beach, editor of the Scientific American and president of the Postal Progress League, is attracting attention more than ever to this movement which it is hoped will lead to increased postal facilities which will place the American producer on a par with his brother in Europe, in the one particular at least, that he may be granted the privilege of shipping his lighter and more compact products through the mail. Practically all of Europe has this privilege and in fact some nations have made arrangements with express companies in this country, so that parcels of several pounds weight are sent by post from those countries to San Francisco or Los Angeles at a less rate than it is possible for an American to send a similar article to a neighboring town.

It is astounding that such a condition has been permitted to exist as long as it has, but the grip of the express companies upon our legislators, combined with unreasoning prejudice of small shop-keepers the country over, holds back this step in advance.

Amongst the advantages which the League in California mentions as possible with the securing of Parcels Post, we may be permitted to quote the following:

As there are at present, at least 40,000 more postoffices than express offices in the United States, those sending packages will have a more complete service.

The farmer can send his produce in small quantities direct to the consumer at small cost and better profit.

The store-keeper will be enabled to replenish his stock more frequently and quickly, not having to meet expensive express charges. Not being obliged to keep on hand large quantities of goods, he can have a greater variety.

Delivery of goods to purchaser will be greatly facilitated, and in many cases with more economy than by private wagons, especially in suburban and rural districts.

Parcels Post presents so many advantages that in countries where it has become an established institution, so general is the satisfaction given that any one who would advocate its abolition would be regarded as insane.

BLOSSOM FESTIVAL.

The people of Saratoga are keeping open house this week, to all their friends, on the hillsides of that beautiful little suburb of the city of San Jose. The writer well remembers an experience at one of these blossom festivals a few years ago and with much pleasure. The hills were covered with prune trees, which with their blossoms, made them as white as the driven snow. This with the background of green, as the hills rose to the mountains beyond, gave a picture never to be forgotten.

This custom of observing a day which commemorates some feature or event of a community is worthy of more general observation in other towns of this state. There are but very few which observe such a day, but we may mention Lodi with its Grape Festival, Pasadena with her Tournament of Roses, Los Angeles with her Fiesta, Escondido also with a grape day, Cloverdale with her citrus fair, which is more in the nature of a festival or neighborhood gathering, likewise the Tulare Citrus Fair, which is becoming a great feature.

Let this list be extended, as in fact there are some other sections observing these festival days, but greater numbers, especially in fruit growing districts, should honor their products in this way. It is good advertising; it creates good fellowship, and increases the pride of the people of the community.

BEST FOOT FOREMOST.

We note in Sacramento valley papers, reference to the planting of orange trees on railroad grounds and near, where tourists passing through on cars will observe them. There can be no question, the orange is a most attractive fruit to the Easterner and we believe that which will secure the attention of the visitor to our state and make a favorable impression should be used in every way possible. Not only the planting of orange trees but the parking and beautifying of grounds near depots will be a most valuable asset to the community.

Too often visitors to a town, lands in the most objectionable section. We recall several places in this state where Chinatown with warehouses and other unsightly features are in the immediate foreground as one alights from the train. An attractive approach to any community needs a little thought and attention; but once the proper conditions are secured, the expense is an extremely small factor.

Plant orange trees, but do not stop there. Plant everything which will add to attractiveness and plant it in such a way that it will be attractive and not a mere jumble of planted things.

LOWER WATER RATES.

The steamship war is on and we are promised lower rates on many products which can be shipped by water from California to eastern points via the Isthmus. This will be an advantage to those shipping to Atlantic Coast points. We trust it will stimulate the dried fruit market so that the present supply may be reduced where it will do the consumer the most good.

WORTH CONSIDERING.

We have seen the statement that "were American officials as wide awake to the importance of rural highways as the officials of France, the gain to the American farmers would exceed a quarter billion dollars annually."

Of course "a quarter of a billion" means nothing to most of us. That is, its immensity is such that we can not conceive of it. But if our readers will divide it up into their own conception of a little fortune, it will be seen that in that amount of money possible to be saved are several thousand independent fortunes.

To be sure the saving of that vast sum will cost the investment of other great sums of money and of effort.

But this effort should be made. It is a crying need. The percentage of improved roads in the United States was but 7.14 of the total mileage, or that approximately only 150,000 miles of the total mileage of 2,150,000 has been in any degree improved.

Nations of the old world wonder why we are so far behind in this important public improvement.

It is especially worthy of note at this time that from the very dawn of civilization the nations which have ruled the world have lead all others in road building and road maintenance. If the links in this historic chain are to bind the United States to Egypt, Babylon, Carthage, Rome and France, a few hundred thousand miles of perfect highways must be laid without delay.

The time for an awakening is here, and the quicker the awakening occurs, the greater the benefit the farmer will enjoy.

FARM NAMES.

We are in receipt of a communication from Assemblyman Lawrence H. Wilson, of the Sixteenth District, in which he encloses bill which has been enacted and signed by the Governor and will take effect May 9th. This bill provides that "any person may adopt a name for any farm or estate owned or leased by him, and register it in the manner provided for the registration of trade marks. Such registration shall have the same effect as the registration of a trade mark. Any person selling or marketing the products grown on any particular farm or estate may use the name of such farm or estate as a trade mark on such products, in the same manner as provided for other trade marks in Section 3196 of this code, and subject to the same rights and duties as provided in this article."

All our farmers should take renewed interest in the naming of their farms, especially as there will be allowed but one farm in the State, as we understand it, to secure this trade mark privilege, of the same name.

WOOL TARIFF.

A live stock association located at Chicago sends a post card stating, "We have reliable information a strong effort is being made by respective interests to reduce duties on wool and hides." We have also heard from other sources that wool especially will not be interfered with in any way by the tariff revision. What the grounds for the statement on this post card are we are not informed but it is well for wool and live stock people to be awake to the situation and know whether a fight should be made to protect the industry by inducing Congress to let the present tax remain. The card states "a change in the present tariff would check the flow of immigration to the country," a strong point to be considered by the nation at large.

PORTOLA FESTIVAL.

We have received from the Executive Committee of the Portola Festival, to be held in San Francisco October 19-23, a statement that work has begun on the plans for a festival in honor of Gaspar de Portola. Portola was the first Spanish governor of the state of California and the discoverer of San Francisco bay. It is expected this festival will attract many people to the state and educate many in its early history.

Agricultural Notes of the Pacific Coast

Northern California

Humboldt county is appealing for a good roads movement.

Farmers at Oroville are petitioning for more farm telephones.

Heavy planting of potatoes is the order of the day at Live Oak, Sutter county.

Maple Creek in Humboldt county is showing less salmon running in the creek than usual.

Tehama county farmers rushed their late plowing and much spring barley has been seeded.

The olive oil and pickled olive industry of Corning is one of the leading features of that section.

The potato famine which was promised to materialize a few weeks ago is not so serious as was anticipated.

Vernon, Sutter county, was visited by a severe wind storm a few days since, doing little damage however.

The Cow Testing Association under process of formation at Ferndale held a meeting recently at which constitution and by-laws were adopted .

Extensive plowing is being done in fields which were overflowed during the earlier storms in District No. 70, below Yuba City, Sutter county.

The annual report of the Western Yolo Consolidated Creamery and Ice Company shows an annual production of nearly 23,000 pounds of butter.

The "peacherine," which is a new fruit introduced by a fruit grower near Stockton, is claimed to be selling well for this season's planting.

A bill passed by the State Senate has placed a tax limit of 2 cents a head upon migratory sheep. The present law authorizes a license of 5 cents.

A. E. Bourke claims he has the largest order for newly-hatched chicks ever given to one breeder. The order is for 15,000 White Leghorns to be shipped from Petaluma.

A proposition to irrigate the lands on the east side of the Ukiah valley in Mendocino county will greatly increase the productiveness of about 3000 acres of land.

George Shima, the Japanese "potato king," has recently secured a lease on 4300 acres of land along the San Joaquin river. He pays a rental of $19 per acre per year.

The suggestion is made that the railway yards through the Sacramento valley be planted to orange trees, so as to impress the tourist with the possibilities of the country as a citrus producer.

The Sacramento Drainage District, which at one time borrowed $25,000 of the state and later succeeded in having a law passed disorganizing the district, will now be compelled to pay the $25,000 which was borrowed.

The State Fair Association has arranged with the Oregon State Fair and the fair at Portland, one at Seattle and one at Boise, Idaho, to arrange the fairs so as to make a circuit of dates which will not conflict.

The weather forecaster at Sacramento has received reports from the snow regions of the mountain districts showing more snow at the head waters of the Yuba, American, and Feather rivers than there has been for years.

Central California

Salinas, Monterey county, is planting extensively of alfalfa this season.

Schools at Kern City observed Arbor Day by planting trees in the school grounds.

One of the most progressive farmers near Salinas is improving moist land by drainage.

Madera has the newest Local of the Farmers Union recently organized. P. C. Thede is president.

The Sunflower Creamery near Poplar, Tulare county, made 245,000 pounds of butter last year.

Visalia has a nervy thief who takes plants and trees which have been planted in orchard or yard.

An apple grower near Porterville is hauling some exceptionally fine apples and shipping to valley points.

Forest rangers from General Grant Park report great depth of snow in many portions of the park yet.

Lindsay still has a few oranges going forward, though the greater part of the crop is already marketed.

Hay growers near Salinas have disposed of large quantities of hay during the last few weeks of high prices.

An extensive planting of eucalyptus will be made on a tract of land near Madera. Five varieties will be planted.

Swarms of flies are making life miserable for farmers and stockmen between Knights Ferry and La Grange.

A co-operative creamery is the latest move at Kerman and it is hoped its early establishment will be accomplished.

The County Live Stock Inspector of Tulare county is placing large placards on the farms infested with Texas fever tick.

Investigations made by agents of the California Canners Company go to show that the coming crop will be exceptionally large.

The State Senate has refused to pass the Stuckenbruck bill which called for the removal of the protection from the meadow lark.

Some blossoming peach trees through the valley have been touched by late frosts and it is feared the crop will be materially shortened.

A bill recently passed by the Legislature transfers much rich land in what is known as the Laguna de Tache from Fresno to Kings county.

The fruit packing interests of this state have determined to make a fight against excessive freight rates and if necessary will use steamers by way of Panama.

At a recent meeting of the San Jose Grange an extensive discussion of the dust spray was entered into. The feeling prevailed that as yet the results are uncertain.

The Kern County Land Company has arranged for an exhibit at the coming state fair which will be in charge of a special agent qualified to explain the merits of that country.

Saratoga, Santa Clara county, is making great preparations for its blossom festival which will be given when prune blossoms are at their fullest, which probably will be either this week or next.

Southern California

Santa Ana has a live Farmers' Club.

Mecca is making a fine display of home grown dates.

Inglewood poultry people held a poultry show last week.

Choice citrus groves are in keen demand at Arlington, a suburb of Riverside.

The silk industry is being attempted on quite a large scale at Riverside.

A Bee keeper near San Fernando reports the bees doing exceedingly well.

Redlands claims the most perfectly fitted orange packing house in the country.

Arroyo Grande, San Luis Obispo county, is making a campaign for better roads.

Two thousand acres of land are all ready for planting to cotton in Imperial valley.

The Imperial County aDirymens Association is a prosperous co-operative organization.

has passed resolutions instructing the board of directors to oppose its passage as far as possible.

Antelope valley feels that the grain crop of the coming season is assured from present appearances.

The output of wool from Imperial valley during the past year is estimated at about 175,000 pounds.

The latest estimates on sugar beets planted at Oxnard are that it will aggregate not far from 17,000 acres.

A shipment of cotton seed from Texas has been destroyed because of coming from weevil infested sections.

Work has been begun on an irrigating ditch to convey water to lands in the Santiago canyon, Orange county.

California Development Company is planning for handling greater water supply for Imperial irrigators than ever before.

The Sierra Madre mountains are reported to be stocked with ice and snow to an extent greater than for many years.

Imperial valley is shipping from 40 to 50 crates of asparagus to Eastern markets daily. These are commanding about $12 per crate.

The directors of the Imperial Valley Milk Company have sold nearly all the stock necessary for the construction of a milk depot.

One cabbage grower at Coachella took a flyer in cabbage this year and as a result of three acres planted has bought 20 acres of land.

Articles of incorporation of the Santa Ana Dairy Farm have been filed in Orange county, for the purpose of supplying milk to the city trade.

The latest method of showing kindness to horses is the establishing of a farm home for decrepit horses to be located near the city of Pasadena.

Santa Ana valley irrigators are in arms over the possible passage of the Black bill in the State Legislature. The Santa Ana Valley Irrigation Company

Shipping of vegetables has dropped off somewhat at the Wanda, Orange county packing house, but shipping of citrus fruits has greatly increased. It is reported that spring peas will be shipped about April 10.

The Coast

Next year's Dry Farming Congress will be held at Billings, Montana, in November.

The dry farmers of Colorado have promise of one of the most successful seasons.

White Salmon valley in Washington boasts of having a parsnip five feet and ten inches long.

Apple growers near Dayton, Washington, find themselves compelled to spray at least once each year.

A bill has been introduced into the Arizona Assembly making a new county out of parts of Yuma, Maricopa, and Yavapai.

The people at Yuma are giving theatre benefits and otherwise endeavoring to raise the money for the Laguna Dam celebration.

The State of Utah is making a proposition to the territory of Arizona to purchase that part of Arizona lying north of the Grand Canyon.

Farmers in Washington are making an appeal to the Legislature to increase the appropriation for the Agricultural College of that state.

A large delegation of Colorado sugar beet growers appeared before the Ways and Means Committee to urge the retention of protection on sugar.

The grange which boasts of the largest charter membership on the coast is located at Scio, Oregon. It started with a charter containing 204 names.

An interesting and practical meeting of fruit growers was held by the Spokane County Horticultural Society at Spokane recently, the principal feature being a practical discussion of pruning of fruit trees.

The Agricultural Demonstration Train now touring western Oregon has a fully equipped chicken house and yard on board, or rather a flat car is given over to the chicken ranch and made a part of the exhibit.

The Farmers Demonstration Train in Washington has a novelty in that its speakers' platform is arranged on a flat car while over the flat car are arranged apple trees which are used to demonstrate the principls of pruning.

Experiments made at the station near Phoenix, Arizona, in the breeding of Tunis lambs are proving quite successful. The flesh of these lambs is very white and is said to have a gamey flavor which makes the mutton in good demand.

A circuit of wool sales has been arranged for the principal wool buying points of Eastern Oregon as follows: Pendleton, May 24-June 4; Heppener, May 27-June 18; Baker, June 5-22; Enterprise, June 25. It is claimed the price will average at least 25 per cent. better than last year.

At the short course for fruit growers at the State College at Pullman, Washington, this winter, the most instructive feature was demonstration trips into field and orchard. For instance, an article on pruning was followed by a visit to nearby orchards and a misshapen tree was taken in hand by experts and its pruning demonstrated before the attendants at the school.

Don't Forget Quality

MIDLAND Poultry Food

Is based on ***quality*** and it is quality in Poultry Food that produces eggs. ***Cheap filler*** and ***cheap grain*** will ***not*** make eggs. ***Midland Poultry Food*** contains only the ***choicest*** cereals and animal food the market affords. You ***can't*** afford to try and be successful and not get results. ***Midland Poultry Food*** will produce results. Try it and see. $1.95 per sack

Petaluma Incubators and Brooders

Are still here, after others are gone. ***The Standard of the World Machine.*** Winners of ***more prizes*** awarded by ***World's Fair Judges*** than any other make.

Remember, we make a hot water machine. One of the ***best hot water machines*** on the market.

Poultry and Live Stock Supplies

We have the MOST COMPLETE and up-to-date supply house on the Pacific Coast. We are agents for the Petaluma Incubators and Brooders, Midland Poultry Foods, etc. We have everything required for Poultry, Stock, Dogs and Birds. Send for our catalogue; it is free.

Berrar & Robertson, 103 East Santa Clara St., San Jose, Cal.

When the chicks are hatched don't feed them anything for 24 hours, then feed them the best dry Chick Feed you can get. We say that is

West Coast Chick Feed

Read what others say:

SAMUEL R. KELLAM, former president of the L. A. Co. Poultry Association, says: "West Coast Chick Feed is the best feed for young chicks I have ever used. I have given this feed a thorough test, and have always found that it produced fine, large, healthy chicks."

MRS. A. BASLEY, the celebrated poultry authority, says. "I want some more of your West Coast Chick Feed, for it is excellent. It is purer, cleaner and appears better balanced than other feed I had been using, and to tell the truth, I have been experimenting, feeding both together, and they always eat yours in preference."

Ask your neighbors, for there is more of "West Coast" sold in Southern California than all other kinds put together. If not sold by your dealer send us $3.50 and we will send a 100 lb. sack, freight prepaid within 300 miles.

West Coast Mill

705-709 So. Griffin Avenue, Los Angeles, Cal.

Count Your Chicks Before they are Hatched!

Profit in the Poultry Yard

By Mrs. Frank Metcalf

We solicit short articles of a practical nature from the fancier and utility breeder, giving their experience with poultry. All inquiries pertaining to feed, management, disease and its prevention will be answered through these columns.

METHOD OF POULTRY RAISING.

(Continued from last Week.)

IT won't do to grease the hen while sitting, as a drop of grease will kill the unhatched chick double quick, as a neighbor of mine once found. She found her sitting hens were lousy and doused the nests, eggs and all with kerosene. Of course none hatched.

Care for the Little Ones.

Bowel trouble is another great cause of chicks dying, and is due to many causes. Sour food is one, and much of the feed we buy has been over-heated in the bin. Never feed to chicks anything that has a musty smell, neither feed them moldy bread. Over-feeding often causes bowel trouble, but where they have food before them all the time there is little danger of their over-eating. It is when they get very hungry and eat too much, the trouble starts.

If they droop, don't eat, and die after a few days, open one, and if the trouble was due to too rich food or too much of it, the liver will have little yellow spots on it and be enlarged, and dark-colored.

Raw eggs, mashed up shells and all, mixed with bran and meal, are far better than hard-boiled eggs for baby chicks, and will sometimes correct bowel trouble. Why not, when we use them for calves?

Lice.

For body lice on old birds, President Bryant of the American Poultry Association once gave me a pointer. We were attending the meeting at Rochester, N. Y., and I was about to buy an evil-smelling louse powder offered there. He called me aside and said "Don't put that stuff on your chickens and have your coops smelling like a disinfecting shop, but get two ounces of sweet oil and one ounce of oil of sassafras and put both into a machine oil can. Apply a few drops under each wing, on the head and around the vent and the birds will smell like a posy garden and not a louse can stand it."

Well, we all know that good perfume will keep moths out of clothing just as well as mothballs, so why not? And back east we always got sassafras poles for hen roosts when we could. Perhaps eucalyptus poles would be equally as effective. I sometimes make a strong tobacco tea and give my birds all a bath. I am sure it paid well, but shall try a bath of eucalyptus leaf tea some day.

Don'ts.

When I was a young girl, I once attended a lecture on physiognomy, and the lecturer pointed me out as having the typical nose of a scold. I didn't like this a bit, but have never been able to trade off the nose, so cannot finish this without a few don'ts.

Don't hatch out a lot of helpless little chicks, and then let them suffer for care. This is done so much, that if the ghosts of the poor little ones that have died for the want of food or water or warmth should arise before us, we couldn't see daylight. I have sinned myself, and know how other cares conflict with the care of chicks, to say nothing of an occasional pleasure. Why, one evening we had company to tea, and I lingered a little too long, and found one brooder lot bunched and 15 dead. Another time a piano agent came along as I was putting them up for the night and I listened to him just a minute or two, and lost a dozen while my back was turned, so quickly will the mischief be done.

Children and Chickens.

Don't try to raise too many chickens while you have little children needing your care. There is where so many of us sin. If motherhood was better cared for there would be less talk of race degeneration, but a man who wouldn't work a fine brood mare, will be blind to the results of his wife's hard work upon what should be more sacred, his own begotten child, and the woman works on, sometimes unnecessarily, sometimes, God help her, because she must.

A woman I know one day went out to feed her chickens and left two little children alone in the house. When she returned she found the three-months-old baby in convulsions because the elder one had poured carbolic acid all over its face, thinking she was giving it medicine. All the chickens in the world couldn't console that mother for her baby's death.

Sweeten the Ground.

Don't raise your chicks on the same ground two years in succession without plowing up. Change them to fresh ground often while growing if possible. A piece of ground can be gardened a few months and be in fine shape for chicks. Don't envy the breeders of fancy poultry and think their big prices are all profit, for their expenses are many. If you buy a sitting of fancy eggs, don't expect every one to hatch a prize winner, for it can't be done.

Don't let discouragement sour you. Mrs. Wiggs said she prayed that she might never get sour, whatever came; so let us cultivate cheerfulness and remember the motto: "Blessed are they who expect nothing, for they shall not be disappointed." It's a splendid motto to set a hen by.

THE SEX OF EGGS.

Time after time the question as to whether it is possible or not to either determine or ascertain the sex of a fertile egg crops up, and time after time the ebullition subsides again without getting any "forrader," so to speak, and we are fain to acknowledge,—at least, the majority of us are,—that it is not possible to say with any degree of certainty what sex of chicken any certain egg will bring forth.

I find that generally there are more cockerels in the early hatches than in the late ones, and this is as far as my own knowledge carries me upon the subject; but as the matter itself has important bearings, if only it could be mastered even in a feeble way, it can do no harm to note a few of the theories advanced. A very

popular belief but one that is fallacious in practice, notwithstanding the assertions of some of its votaries, is that round-ended eggs produce pullets in the main. Were this so, round ended eggs would be at a premium among breeders, and the price of table fowls would rise. Another, though far less popular theory is that eggs set directly after being laid will produce pullets, while if kept for several days cockerels are most likely to be hatched. If there is anything in this theory many of our breeders would prefer stale eggs to fresh for sitting purposes. A theory that any fowl keeper may prove or disprove to his own satisfaction is that connected with the "lie" of the egg in the nest. Should the pointed end point towards the north it means a cock. This is as the hen leaves it after laying, and if the poultry keeper will only take the trouble to go round his nests, compass in hand, marking the eggs as gathered, he should be able to tell subsequently whether or not the theory will bear the light of investigation. As nothing is said of the eggs pointing betwixt and between, these had best be ignored during the test.

Some hold the more vigorous the male the more numerous the cockerels. A non-vigorous male means plenty of infertile eggs, but plenty of cockerels generally come in proportion to the number of eggs hatched out. Some, again, assert that for breeding plenty of pullets, the females being very vigorous means success in the matter; but as yet this has not been conclusively proved. An unproved theory connected with fowls in small runs is that the withholding of meat during the breeding season means that plenty of pullets will be forthcoming from the eggs that may be hatched. This may be easily tested and is about as reliable as the majority of the theories mentioned, which, I am afraid, is not saying much in favor of its answering well in practice.

Neither is there much reliance to be placed in the theory that eggs laid late in the afternoon or during the night will produce pullets; or in the one that more pullets may be expected from penned fowls than from those running at large. Another theory that has nothing whatever in it I believe, is that first crosses mean a preponderance of cockerels, while a second cross means pullets. As to whether mongrels or pure breds are the more likely to produce pullets I do not remember ever having heard an opinion upon. Some declare that young fowls produce the most cockerels; others that the contrary is the case, namely that if cockerels are wanted good old stagers should be put up for breeding purposes. Some, again, say that one should mate pullet with an old cock, others mate a cockerel with old hens when wanting eggs that will produce pullets. Some say that in-bred,—hard in-bred, that is—fowls are to be relied upon for production of eggs that will bring forth considerably more pullets than cockerels, while other poultry keepers hold that pullets are most likely to be in the majority if the parents have had as much fresh blood as possible bred into their veins for generations, also taking care that when making up the breeding pens the sexes are entirely unrelated. I have not tried the former plan, but know from experience that there is no truth whatever in the latter.

There are probably many other methods advocated as having a bearing upon the sex of eggs, and there have been, I believe, some experiments made with X-ray and other media with the idea of gaining some clue as to whether sex could be foreseen or not; but whatever the future may hold, we are so far in the dark as regards an even approximate certainty of the sex of a fertile egg. But, although we do not as yet understand the subject, we have hopes that sooner or later the problem will admit of solution . I believe, though it is only my own personal belief, and carries no conclusive weight, that with effort and perseverence it would be possible to establish a strain that would in the main produce pullets and although the task would be a by no means easy one, when once established, such a strain would repay all efforts. At the time of writing, rumors that a method of turning cockerels into layers is to the fore; but I confess that I have doubts about the practicability of the

First Prize White Wyandotte Cock at late Breeders Show. Owned by A. W. Huskins, Los Angeles, Cal.

$100 Cash Free to You

I sell "SUCCESS" Incubators on trial. I guarantee to refund the money after you use the machine if you do not find them to be exactly as I claim. No other company in this state will do this. Up to this date March 15th, not a single customer has asked for his money BACK either on a "SUCCESS" INCUBATOR or a "SUCCESS" Brooder. I will give you $100 cash if you prove this statement is not true. Is this a good record? Does it not prove that these machines are what we claim them to be? Does it pay you to spend from $5 to $20 more than we ask for an Incubator that will positively give you a good hatch EACH and every time. Some incubators hatch good once in a while, ours hatch EVERY TIME if the eggs are reasonably good. I make

Fireless Brooders

that will raise every healthy chick.

I handle over 240,000 chicks yearly through the Pioneer Hatchery, I know how to BROOD them. Send for FREE catalogues and circulars.

268 East Market St., San Francisco, Cal.

scheme. Should such a thing turn out to be possible, then there need be no further discussion as regards the sex of eggs. Meanwhile there is a chance for any enthusiastic poultry keeper with plenty of spare time to commence investigation of the egg, and it may be that sooner or later some very simple method will be found of determining with something like certainty, whether a given egg, if fertile, will produce a cockerel or a pullet.

It is hard to say upon what lines the egg should be tackled, but I should think that at any rate weighing, immersion, testing in lights of various strengths, tint, and origin, and other expedients of a like nature, should be given a more or less extended trial; and by the time that all this has been gone through, the experimentor would be better able to say upon what lines future investigation should turn than we are. During the whole of the experiments copious and careful notes should be taken and no pains spared in fully verifying any conclusions that might be come to. Then care should be necessary in the keeping of the various hatches of chickens separate and easily identified until there could be no mistake about the sex of the birds. Of course, an anatomist would tell the sex at any age, but I am presuming that the chickens are in ordinary hands and intended to be reared in any case. If kept simply for the purpose of experiment, probably a breed,—say, Leghorns,—in which the cockerels may be picked out at an early age would give most satisfaction, though any breed would answer the purpose. And then should the experimentor be persevering enough or lucky enough to discover the secret, he would prove a benefactor to the poultry world, and would himself become immortally famous.—Poultry, England.

POULTRY QUERIES.

Brooders and Houses.

I am thinking of going into the chicken business to some extent. I want to keep 200 or 300 hens on hand. Please give me instructions: 1. For a fireless brooder to hold chicks from a 300-egg incubator; 2. What is the greatest number of chicks one can put in each compartment of the brooder? 3. How large will each apartment have to be to accommodate a certain number of chicks? 4. How long do chickens hatched April 1st have to be in brooder or under hens? 5. Which is the best plan, to keep 200 hens and sell 100 every alternate year, when 2 years old, or 300 and sell one-third every year at 3 years of age? (I intend to sell 100 and replace 100 each year) 6. How many inches is needed for each hen on the roost, and what space shall I leave between roosts? 7. What is the greatest number of grown fowls that I can keep in each house if they have free range in day time?—A subscriber, Dinuba.

The above list of questions looks like business. Here is a man who intends to succeed, and he will not go at it blindly, therefore he will "make good." 1. A fireless brooder is simply a box about 18 to 20 inches square, and from six to ten inches deep, with tight floor and a little door for the chicks to go in and out on level with floor. A frame is placed over the chicks, held in place by cleats and having cloth of different kinds tacked loosely on so it will sag over the chicks' backs, and air provided for above this cloth in various ways, some using augur holes and some just cracks, and chaff cushions or extra covers over this cloth, and chaff or cut straw under the chicks. This must be placed inside a building of some kind and is simply used for a hover. The best way is to buy one already made and copy it. 2. Not over 50 chicks should be put in one of these brooders and 25 is still better, as they will have to be divided as they grow, if too many are put together. Say 50 the first two weeks, then either move them to a larger brooder or divide them. 3. A 20-inch square compartment will brood 50 chicks for four weeks. 4. Much depends upon the breed. Some breeds feather out so much quicker than others, and such can stand being weaned from hens or brooders very much younger than those feathering out more slowly, say from four to six weeks, while the bare-backed ones will need heat (mothering) some two weeks longer. 5. Would sell half the hens each year, whether I kept 100 or 1000. 6. Allow from six to eight inches space on the roost for each fowl, according to size, the larger breeds, of course, requiring more room than the smaller ones. Roosts should be 15 inches apart for small breeds and 20 for large ones. 7. 50 should be the limit for each house.—Mrs. Frank Metcalf.

Swell Head.

Could you tell me through the Cultivator, what is the matter with my chickens, five weeks old? Their heads swell up all over, especially around their ears, and under the throat. It is not at all like roup or sore-head. They have no colds, eyes and nose do not run and they have no offensive odor. In all my experience with poultry I have never had anything like it. They have free range, but run principally in a garden where there is a great many cabbages and turnips. They have plenty of fresh water and grit, also alfalfa. I feed Kaffir corn whole. Please tell me what is the trouble and what to do as they are thoroughbreds and I am in despair. The inside of their throat and mouth look all right; all the swelling seems to be on the outside of head and throat; even the back of their heads is swollen.—M. B., Brawley.

Your chicks certainly must have "swell-head" caused by either too close housing at night and chilling in consequence when let out, or it may be caused by draughts blowing upon them during the night through a crack or knot-hole. Would grease their heads well with vaseline or lard in which a few drops of camphor has been worked. And I should certainly stop feeding Kaffir corn, and feed cracked wheat and corn and be very sure the feed was free from musty odor and that their house was kept dry and clean.

Camphorated lard is excellent for taking the swelling out of anything, and should be used freely and always kept on hand.—Mrs. Frank Metcalf.

Turkey Eggs.

Where can I get 100 turkey eggs?—A. E., Lynn, Rosamond, Kern County.

Mrs. Hubbard, San Fernando, and other advertisers of the Cultivator can supply you. However, any other turkey breeder who has large quantities might do well to place his announcement in the Cultivator as there seems to be strong demand for turkey eggs this season.

Control of Sex.

A writer from Redlands, referring to a recent query as to control of sex of eggs, says: "I can tell you that I have found that with few roosters the hatch will show more roosters than pullets and vice versa."

POINTERS ON GEESE.

Care and patience will bring success.

Geese must have freedom to thrive well.

Pure breeds are always to be preferred to crosses.

For best results, all changes in mating should be made in the fall.

Geese are unusually hardy and subject to no particular disease.

Keep the stock gentle and tame, and they will turn in more profit.

Two or three year old geese are more profitable than yearlings.

A mating can be continued for seven or eight years without a change.

If the geese have confidence in the feeder they will be very friendly with him.

From ten to twenty eggs are laid

before the goose shows a disposition to sit.

Shelter should be provided where the geese may go during inclement weather, and especially at night.

A bird with a yellow or orange colored bill, is always preferred by the Jews in purchasing geese in the market.

The Rhode Island Experiment Station says in handling geese they should always be taken by the neck, and when lifted from the ground the body should be turned with the back toward the person handling it. In that position it cannot strike, and will remain quiet and docile. The body can be partly supported by seizing the first joint of the wing with one hand. If the goose is held facing one, it will strike hard blows with its wings, or scratch with its feet.—The Feather.

CHARCOAL FOR FOWLS.

Having charcoal where the fowls can get it when wanted will tend to keep their digestion in fine order. In fact, where mistakes are not too pronounced, charcoal will correct them and keep the fowls in good condition. Even when the fowl is all right, there may be times, owing to other causes, that a hen's digestion will get out of order. If, however, she can get charcoal to eat, she will, as a rule, soon be back to a normal state. If any portion of the farm is being cleared up and there are many large fires made from heaps of brush and wood, particularly of green there will be found among the ashes pieces of charcoal. While these pieces may not be just the same in composition as the purchased charcoal, they will be found to answer almost as well when crushed and given to the fowls. In buying charcoal, get the coarse ground kind. This can be placed where those fowls that want it can get it. On the other hand, if powdered charcoal is used, it will have to be mixed with the mash and all will have to eat it. Some fowls do not require charcoal and therefore the results may not be beneficial. Growing chickens as they near maturity are voracious feeders and sometimes cause trouble for themselves from overeating, when they get an opportunity to do so. Keeping charcoal where they can reach it will help to prevent trouble in this regard.—Orff's Review.

TABLE POULTRY.

As a general thing it takes about three to four months to grow a broiler, depending upon the weight wanted.

For shrinkage in dressing broilers an allowance of about a half pound each should be allowed.

It is a mistake to ship to market poultry that is not of good size and in good condition.

Too great care cannot be taken in killing and dressing poultry, to avoid bruising. Discoloration quickly follows a bruise.

There is a chance for skill and energy in the broiler business, and when applied there is profit for the grower.—The Feather.

Expensive poultry houses are for the rich and should hinder no one from going into the business.

Do not set eggs from the small breeds under large hens, because they are likely to break them.

"Success" FIRELESS BROODERS

150-Chick Size, $5; 50-Chick Size, $3. We Pay Freight

For over a year we have been making experiments with fireless brooders, and we have our fireless brooder perfected now and ready for sale.

For some time we have been selling these brooders as fast as we could make them here in the city, and there was no use to advertise them. However, we have now installed machinery for this special purpose and can turn these brooders out very fast and at a price much less than you could make one of them. I am anxious to get them introduced everywhere quickly, and in order to do so, we will make you the lowest price ever heard of for a first class well made brooder. This is not a rough lumber brooder, but it is made from first grade kiln dried redwood lumber, nicely stained mahogany color, and is light and can be easily moved from one place to another. It weighs ready for shipping just 25 pounds. Holds 150 chicks, and will raise them to three weeks old, and will raise 75 to six weeks of age. We also make a 50-chick brooder which weighs 15 pounds, holds 50 chicks to three weeks old and will hold 30 to six weeks old. After chicks are three weeks old, you can make a box to hold them as they do not require much heat to raise after three weeks.

If you will take my advice on the fireless brooders you will use the 150 size, as by putting at least 75 chicks or more you will have better luck, I honestly believe, than with a small 50-chick brooder. The reason for this is that 100 or 150 chicks will keep warmer than fifty chicks. These brooders can be used either indoors or outdoors, but for the first week they should be kept in a room where it would be comfortable to sleep. Some companies will say that you can put them right outdoors; you can, but if you do you will chill your chicks sure, I don't care who makes the so-called outdoor fireless brooders or what they claim on paper. Experience will teach you that for the first few days to keep the brooder in some enclosure to help protect the chicks from the cold early mornings. In the day time the brooder can be picked up and carried into the sun easily.

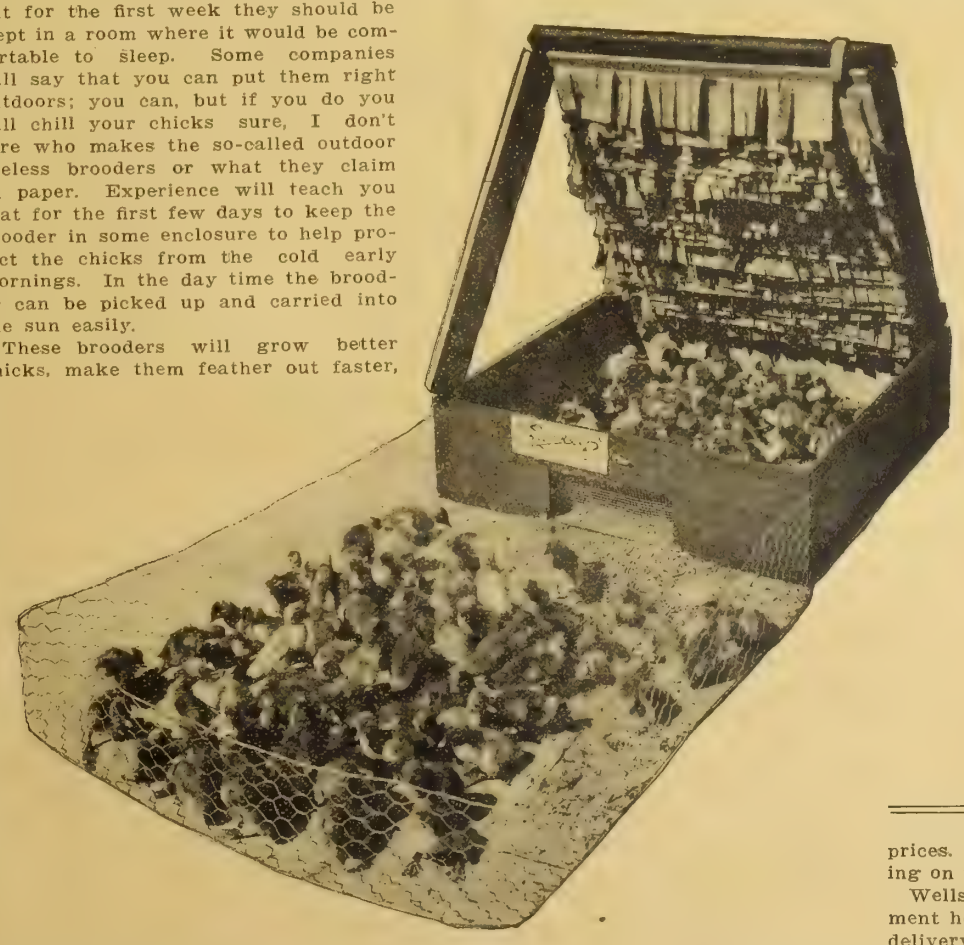
These brooders will grow better chicks, make them feather out faster, and more healthy and strong, than any heated brooder ever made. I honestly believe that all heated brooders made by all incubator and brooder companies will be done away with in the next two years. We make as good a brooder heated by lamps as can be made; it will not raise any more chicks than the fireless brooder, and takes much more time to manage it. There is **NO DANGER OF FIRE,** no lamp to bother with, no oil expense, and you will save more and better chicks than any other way you can brood them. You may be skeptical and afraid to try a fireless brooder, but I will sell you one on trial, if it don't do the work as I say it will send it back and get every cent. I know absolutely that you will raise the chicks if they are reasonably strong to start with. No brooder on earth will raise weaklings from pullets' eggs. Be sure you get good eggs to start with, and then you will know that your chicks will be good when you get them.

With ordinary care and following my simple directions in regard to feed, etc., you will raise 90 to 95 per cent of every lot of chicks you put in the brooder. Try one at my expense, if they don't do the work I will refund every cent. I sell my incubators the same way, not a customer has asked for his money back this year up to this date, March 14th. $100 cash to anyone who proves to the contrary.

I make good incubators and make good brooders. I know how. I am here to help you at any time. Ask me questions. Get my incubator catalogue, and tell your neighbors to send for one.

Improvements

We are improving these brooders from time to time, we are always trying to make better goods. If you receive a brooder that is some different than the one shown here, it will be in the way of improvement. I sell on this understanding only, as I guarantee the brooder and will refund you the price in full if not satisfactory, providing you return the brooder in five days, you know positively that you will get your money's worth and more.



Prices

We make this brooder in two sizes, namely, 50-chick and 150-chick size. The 50-chick brooder is sold at the low price of $3.00 and the 150-chick size at $5.00.

We Pay Freight to Your Nearest Railroad Station Anywhere

If you wish to order chicks from the Pioneer Hatchery Co., 112 East Eighth street, this city, you may buy fifty chicks and get the 50-chick brooder for $2.50, and we can ship the chicks to you in the brooder by express.

The 150-chick brooders sells at $4 when you order 100 or 150 chicks. At least this many chicks must be ordered to get the special price on the brooder. We do not pay the freight when we ship them filled with chicks by express. The express rate is lower when you have the chicks come in the brooder, and as they weigh but little the expense of shipping is small. Customers living in **LOS ANGELES** that wish to order both chicks and brooder, please remember we do not deliver these brooders in the city at the special prices. Cartage must be added, depending on where delivery is to be made.

Wells, Fargo Company calls for shipment here at our door and we have no delivery expense, and that's one reason we can sell the $5 brooder for $4 and the $3.00 brooder for $2.50.

We make small delivery charge here in the city at these low prices, ask about it. If other goods are going in your vicinity no charge is made. Try one or more of these brooders and you will use no other. Come and see them if you can.

Try one "SUCCESS" Brooder and you will use no other

Coulson's
POULTRY FOODS

Special Dry Chick Food

COULSON'S SPECIAL DRY CHICK FOOD, during the five years it has been on the market has justly earned for itself its great reputation as a life-saver for little chicks by its special adaptation to their needs.

THE UTMOST CARE is observed in the selection of each of the dozen or more articles composing this unequalled feed; tender seeds, cracked grains blown free from dust, steel-cut oats, tiny pieces of dried meat and bone, willow and pure bone charcoal, are combined with other very necessary ingredients; every article being selected with special reference to its quality, strength, and desirability for the needs of the young chick.

FOR YOU TO BUY the many different articles composing Coulson's Special Dry Chick Food is quite impracticable; you could not be certain as to their quality for one thing, and the high cost of certain of them when purchased in small lots might lead to their being left out to the detriment of the chick.

TO MAINTAIN the high reputation of COULSON'S SPECIAL DRY CHICK FOOD, nothing is left undone to make it absolutely the best feed that can be made for the little chicks.

COULSON'S SPECIAL DRY CHICK FOOD can be fed exclusively to your little chicks for the first six weeks, at a cost of about four cents (4c) each; and what is of still greater importance, it will do all that can be done in the way of feed to bring them through that critical period of their lives in full health and vigor.

TO RAISE EVERY CHICK you hatch; to have fine, large, healthy chicks; to have chicks that will stand up and crow when eight weeks old; to raise chicks that you will be proud of, FEED COULSON'S SPECIAL DRY CHICK FOOD, THE LIFE SAVER.

BENEFITS OF TRAP NESTS.

We can learn nothing about the hen physically until we submit her eggs to hatching tests. If each egg be marked with hen's number and placed in a pedigree hatcher we learn the following things of each individual hen:

1. That her eggs are either fertile or non-fertile.
2. That they hatch or do not hatch.
3. That her chicks are strong or are weak.
4. The percentage of chicks raised from her eggs.
5. The defects her chicks are prone to.

With these facts for a basis we can:

1. Mate the infertile hen with another cock.
2. We can either remedy the hatching quality or not set them (the eggs.)
3. We can build up hen's vitality or not set eggs.
4. We can seek the reason and try to remedy it.
5. We can breed to remove these defects.

The best laying hen may not lay fertile eggs or her eggs may be fertile and not hatch.

Her chicks may be weak and sickly and live, or they may die.

Her chicks may be defective in many respects. Yet this superior hen would be the most valuable hen, but for these defects, and with the defects removed such a hen pays better than a whole flock of poor ones.

It is only by numbering hens and marketing eggs laid in trap nests and using pedigree hatchers that we can learn anything about each individual hen and her characteristics, and until we do, we work in the dark, darkly.

When feed is expensive the poor hen eats up all profits from the good hen. One-half the flock good, to the other half poor, is a stand-off. Two-thirds poor to one-third good is a loss.

I have seen eggs laid for family use which cost more than if bought fresh.

I have seen laying hens killed for table when the flock had many non-layers.

Ignorance is at the "root of all failures." "We did not know." But the trap nest remedies all that.

When people will recognize that exact knowledge is necessary to success and take steps to learn the physical qualities of each hen, they will have taken a long stride towards poultry success.

People should realize that they may make more money with the one-third good part of their flock than they are making with all. They should realize that the eggs and chicks from a fine layer are worth very much more, if no defects exist than the eggs or chicks from all the poor ones.

Trap nests are cheaply made and with a yard attached may be visited but two or three times daily if food and water be kept in yard.

For myself, I would install trap nests before buying a hatcher, as without them I could expect nothing but failure.—Southern Poultry Journal.

Some assert that sprouted grain can be made the principal food. This is not clearly proven, but there is no doubt that it solves the question of green food and makes it possible to keep fowls in more limited quarters than could be done without it.

Polly Oil

February 6, 1909.

Dear Sirs:—

I have used your Poultry Tonic for a long time and think there is none so good. But you have one remedy, POLLY OIL, I do not feel you know its worth. I had one little sample bottle given me a few weeks ago. I used it on two cases of swell head and it stopped the swelling right away. I had one pullet on which the lump had stayed for over two months, her bill having grown crooked, but as she was a pet I could not have her killed, but could not drive the lump away until I got the sample of Polly Oil. It then commenced to go away, and in a few days it was nearly gone. I have cured every one since that showed any signs of such trouble. I have used all I have and do not want to be without it.

Very respectfully,

FANNIE L. E. WEBBER,
Pasadena, Cal.

If not sold by your dealer send the price, 50 cents, and we will send you a bottle, prepaid. WEST COAST MILL, Los Angeles, Cal.

WATER GLASS FOR EGG PRESERVING

Why sell eggs at 15c a dozen? Eggs kept in this water glass will keep 12 months or more and are as fresh as new laid. Sold in 25c tins for 150 eggs and $1 tins for 1200 eggs. Egg preserving baskets with cage and cover $1 each. There is only one kind of water glass suitable for this purpose and it is on sale at West Coast Seed Co., 115 West Seventh St., Los Angeles.

CEMENT ON THE FARM.

WITH the wonderful development of the Portland cement industry during the past fifteen years comes one of the most ideal building materials ever produced—cement. This is the beginning of the "Cement Age."

The price of lumber is advancing to almost prohibitive figures; it is therefore natural that a substitute material with the advantages of moderate cost, durability, and beauty should be developed and looked upon with favor.

Today, cement can be successfully used on the farm in the place of wood in the construction of floors, troughs, gutters, tanks, ditches, dams, walks, posts, building blocks, etc.

Cement.

Use nothing but the best cement that can be obtained. It should be in a fine, powdery condition and contain no lumps. Cement should be stored in a dry place, as dampness is an element of great danger.

Sand.

The sand used should be clean, sharp, and not too fine. It should be free from loam or clay, as these will tend to destroy the adhesive quality and to retard the setting of the cement. Clay mixed with the sand may be removed, to some extent, by washing.

By sharp sand, we mean that the edges of the grains must be sharp and not round or worn off, as will often be the case in sand found in the bed of a stream. Coarse sand is better than fine sand. Fine sand, even if clean, makes a poorer mortar or concrete, and requires more cement to thoroughly coat the grains. A large proportion of the grains should measure from 1-32 to 1-16 of an inch in diameter. Some fine sand is necessary to help fill the spaces between the larger grains, and will thus save cement.

Water.

The water used should be clean and free from acids or alkalies.

Mixtures.

There are two general classes of mixtures, the tamped, or dry, and the poured, or wet. For the tamped add just enough water so that when all the concrete is in the form or mold and is well tamped, water will show on the surface. This kind of a mixture is usually used for floors, sidewalks, etc. For the wet or poured mixture, enough water is added to make it thin enough to pour from a pail. This is poured into the mold, and the mold must be left on it long enough for the mixture to set, which is from one to two days of summer weather. This last mixture is adapted to use in the construction of fence posts, watering troughs, foundations, etc.

Proportions.

For ordinary farm construction, as the making of floors, foundations, walks, etc., the following proportion is recommended: One part cement, 2½ parts clean, sharp sand, and 5 parts of loose gravel or broken stone. For floors, this should be tamped in to a depth of from 5 to 8 inches. This should be finished with a surface coat 1 to 1½ inches in thickness, composed of 1 part cement and 1½ to 2 parts of clean, coarse sand, mixed. Nearly all constructions which come in contact with water should be covered with a mortar at least as rich as the proportion last named. For engine foundation, 1 part cement, 2 parts sand, and 4 parts broken stone is good.

In estimating the amount of material necessary for a certain construction, do not make the mistake of thinking that a mixture of 1 barrel of cement, 2½ barrels of loose sand, and 5 barrels of gravel or broken stone will make 8½ barrels of concrete. The sand will fill the voids between the gravel or broken stone, and the cement fills the voids between the grains of sand. The total amount of concrete will be but slightly more than the amount of gravel or broken stone used.

To make one cubic yard of concrete of the following proportion—1 part cement, 2½ parts sand, and 5 parts gravel—requires about 1¼ barrels of cement (5 sacks), 3¼ barrels of sand, and 6½ barrels of gravel.

Mixing.

Be very careful in measuring the proportions. Mix the concrete as near the place it is to be used as possible. Use as soon as mixed. Do not mix more than can be used in 20 minutes.

Measure the sand first, and spread it in an even layer in a mixing box; spread the cement on top and turn it with a shovel at least three times. Then add the broken stone or gravel which has previously been wet, and turn the whole at least three times. Begin to add the water on the second turning, not too much at once. A sprinkling pot is better than a hose for adding the water, as it does not wash away the cement.

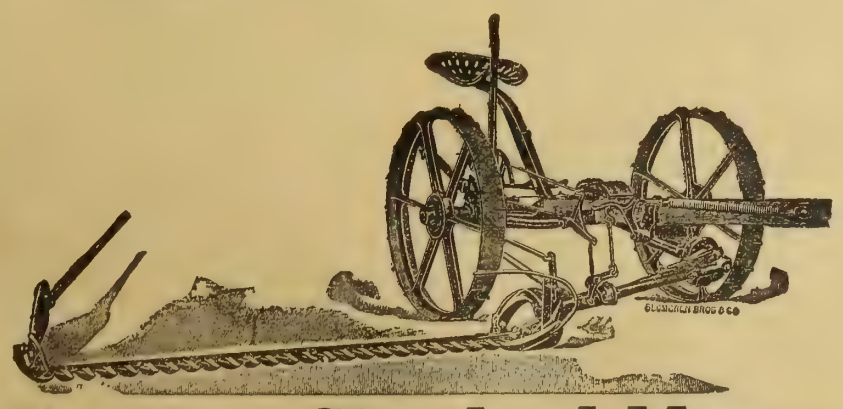
Concrete work should be avoided in freezing weather, as frost damages it. Where it is absolutely necessary to do work at this time, a small amount of salt added to the water will prevent freezing; this does not damage the concrete when used in small quantities.

An objection is sometimes raised that concrete floors and walks are too smooth and become slippery when wet. This fault is largely due to the fact that the finishing surface was completed with a steel smoothing trowel instead of a wooden trowel, smoothing board, or straight edge, which would have left the surface rough. This fault is also overcome, in a great measure, by dividing the wearing surface into small squares, about four inches on each side, by means of triangular grooves three-eights of an inch in depth. This not only makes a neat appearance, but furnishes a good foothold for stock.—H. M. Bainer, Colorado Agricultural College.

A FRICTION STORY

A small boy can slide faster down a smooth, greased board than he can down an ungreased board full of slivers.

MORAL: A mower which comes closest to elimitating friction will require the least power to operate.



The New Standard Mower

The Cutter Bar is curved when raised, so as to be mathematically straight, to form a frictionless channel for the knife, when lowered. This Bar is patented and can be used only on the New Standard Mower.

The entire weight of the Cutter Bar is transferred through the Suspension Spring to the main wheels. The bar is carried—overcoming the friction of a dragging bar which is pulled or pushed on the ground.

Steel Rollers and Steel Balls surround the main shaft and pitman shaft.

The New Standard Mower develops more cutting power from its special high speed gearing and the grip of the main wheels on the ground than is developed in any other mower—although less power is required to operate it on account of absence of friction.

A folder giving full detailed description of the New Standard Mower and our other Haying Tools will be mailed free on application.

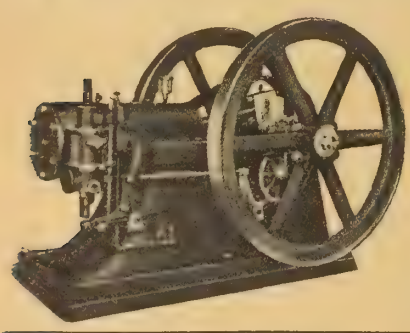
Alamo Gas Engines

For Irrigation Purposes



They are self starting and simple in operation. They are best in durability, appearance and price. They operate at a low cost and develop the maximum power. They embody every improvement in gas engine construction. A full line of repair parts and accessories always on hand. Write for catalog and estimates on complete pumping plants.

Harrison Machine Works

719-21 N. Main St., Los Angeles

VALUE OF COTTONSEED MEAL.

The value of cottonseed meal for producing meat, milk, and butter is well established. It is one of the cheapest of the highly nitrogenous feeding stuffs, and is therefore one of the most economical for balancing rations deficient in protein, such as those in which corn is the principal grain. As the analysis * * * shows, it is very concentrated and should be fed in comparatively small quantities is connection with a large proportion of coarse food, such as silage, corn, straw, corn stover, cottonseed hulls, etc., or with good pasturage.

Although milch cows will do well for an indefinite period on cottonseed or cottonseed meal as the sole grain food, it is better to add a second, such as corn meal or wheat bran, to the ration.

If fed to cows in large amounts without proper admixture of other feeding stuffs, it is likely to injure the quality of butter as regards flavor and color. It appears, however, to harden the butter and thus to enable it to stand shipment better. It has also been found to facilitate very materially the rise of cream by gravity.—From Farmers' Bulletin No. 36, U. S. Department of Agriculture.

EDUCATIONAL BUTTER SCORING CONTEST.

The call for the first entry to the California Educational Butter Scoring Contest brought a response from twenty-four creamery butter makers. Because of careful packing and cool weather most of it reached Davis in good condition. On March 1st it was scored by Mr. C. L. Mitchel, U. S. butter expert of San Francisco, assisted by members of the Dairy Department

Letters of careful criticism will go forth to the various butter makers as fast as they can be prepared.

This is an excellent begining and we hope that the interest shown will be maintained. The next entries will be called for in April. In the meantime the butter makers should prepare to use starters more generally. Those who have done well at this season without starters will need to look to their laurels as the weather becomes warmer.—Herbert A. Hopper, Davis.

Queries and Replies

Questions to be answered in this department should be received at this office one week before reply is expected. Write plainly on one side of the paper and sign full name and address. Unsigned communications receive no attention.

Geological Survey.

Please tell me through the Cultivator where the maps and papers, described in a former Cultivator, spoken of as Water Supply Paper 222 plate 1, may be secured.—A Subscriber, Azusa.

These papers may be had by addressing Geological Survey, Washington, D. C.

Alfalfa in the Orchard.

Is it beneficial or otherwise to raise alfalfa in an orchard of prunes and apricots? I have plenty of water for irrigation.—Subscriber, San Jose.

As a rule orchardists in California prefer clean culture, but if a strip is left either side of the trees and alfalfa planted in the center, prunes and apricots should not be materially injured. Some orchardists in the southern end of the state have cultivated the two crops that way and with good results, always, of course, provided abundance of water is supplied.

Imperial Valley.

Please inform me as to conditions in Imperial Valley, I am told there are strong northeast winds. How much is the rainfall and is there malaria and chills? Is there any dampness like sections near the coast? How is drinking water and where does it come from? Have they thunder showers in summer and is it sultry when hot there?—W. H., Palmdale.

Imperial Valley has its wind storms at times, but we are informed by those living there that they are exceptional. The rain fall is practically nothing, at least so slight that no dependence whatever is placed upon it. Irrigation water is abundant and no crops or trees whatever are attempted without its use. We believe there is practically no malaria, as conditions are exceedingly arid. During the Summer, storms are common in the mountains and at such times more or less humidity prevails and the heat is somewhat oppressive, but as a rule the dryness of the atmosphere makes the heat endurable. Drinking water is all secured from the Colorado River, cleared in settling basins and then it is drawn to cisterns.

Spraying for Fungus.

I was prevented on account of rains from spraying my apricots for shot hole fungus before blossoming time, may it be successfully done yet? The fungus is not as bad here as in the north, the leaves are never affected. I am the only one who is spraying for it in this section. Some years there is none whatever, other years quite bad. I fear on account of the wet conditions favorable to fungus, it will pay to spray this year. Trees are blossoming exceptionally well, and there is promise of an immense crop.—J. F., Santa Paula.

It is unfortunate that the spraying was not done while the trees were perfectly dormant and the stronger solution used; however, the following formula may be used safely on foliage: Lime 4 lbs., blue stone 4 lbs., water 40 gallons. Dissolve the blue stone in part of the water, slake the lime in an earthen vessel and pour the dissolved solution together with the remainder of the water. Stir constantly while pouring.

Spring and Summer Term
at the Polytechnic Business College

Oakland, California

Great Business Activities are Resuming

Opportunities for trained young men and women are now opening up and success awaits every earnest and ambitious graduate of the Polytechnic Business College.

Every graduate of our **complete business training course** for ten years has secured remunerative employment.

Now is the Time to Plan for the Future

Write for free illustrated catalogue and kindly mention the "Cultivator."

White Beans.

Please tell me what small white beans are recommended, what is the average yield per acre and when is the best time to plant.—S. C., Greenfield.

The greater part of the small white beans grown in California are grown in the San Joaquin and Sacramento Valleys. Stockton is the center of the industry. The best time to plant is possibly in May. The yield per acre is sometimes as high as 2000 pounds, usually 1500 or lower. Your other query will be answered in the Veterinary department next week.

Walnut Die-back.

Should the wood on walnuts that has been winter killed be cut back to live wood or let alone to take its own course. My trees are mostly two years old, the curious part to me is that the nipped trees are scattered through the grove next to those that show no sign of frost. They seem to be the thriftiest trees. I undertook to make my trees hardy last fall so they could stand the frost. They were not irrigated after August 1st, but had thorough cultivation until November. Do you advise covering the cut with grafting wax after the limbs are removed, or isn't that necessary.—A. B., Hemet.

The die-back you speak of is not likely caused by freezing, but most likely because the water was taken from your trees too early in the season . This happens frequently among trees that start very vigorously in the spring and are not irrigated at all and as you say the most vigorous trees are most affected because they need the most water.

It is perfectly safe to keep the ground well watered all the time as the trees will stop growing in time to harden wherever walnuts will do well. You can irrigate walnuts thoroughly during the first half of September and have no winter killed branches. If the trees become too dry, so that they will start growing when an early fall rain comes, they are in danger of having the tender growth frosted, but this will not happen if the ground has been kept moist.

Since you have dead branches it will be best to wait until the buds start and then cut back to a vigorous bud that is starting on the upper side of the branch so as to keep your trees upright. You will not need wax on the cuts as they will heal over in a few months if cut within one-half inch of the bud.

The softshell walnuts have always been considered hardy but will not fruit well in the northern part of the state, neither does the Franquette fruit well in the southern part of the state.

Melon Seed.

I wish to grow melons for seed for the market; what is a safe distance to plant musk-melons to prevent cross pollenizing? Also will plant water-melons and would like to know if pumpkins will cross with melons.—G. J., Ripon.

Musk-melons of different varieties should be kept as far apart as possible. We would not say a quarter of a mile, yet we presume that would be a safe distance; even then it is possible that bees will carry pollen from other blossoms; better keep them as great a distance apart as possible. Water-melons may be planted near the musk-melons. On the other hand, pumpkins will mix and give you seed of no value.

This Great World History
SENT TO YOUR HOME FREE

Just send your name and address on the coupon below—that is all you need to do. It does not cost one penny and as soon as your name and address is received a set of the world famous **Library of Universal History** will be sent to you prepaid.

HERE is the greatest opportunity ever offered—an opportunity for our readers to secure at less than half price these fifteen beautiful volumes all printed from large new type, embellished with over 100 double page maps and plans, 700 full page illustrations, many of which are in colors, and over 5,000 pages of reading matter.

This offer is made possible by the failure of the publishers, the Union Book Co. of Chicago. Hundreds of sets of this work have been sold at $60.00 each and they are worth every cent of it, but we now name you a rock-bottom bankrupt price of only 50c after examination and $2.00 per month for 14 months. It is impossible to name a lower price for cash in full, as this is less than half the publisher's price and is made only to close out the few remaining sets quickly.

Before you decide to buy we invite you to examine this work in your own home for an entire week absolutely free of charge, and should you not want the books after examination we will have them returned at our expense. **We earnestly request you to examine this Library;** let your wife and children and friends see it. No better set of books could be placed in the hands of children than this; it reads like a thrilling novel, and is in fact a complete connected History of every country, nation and people from the beginning of time to the present year; the **greatest World History ever written** and endorsed by scholars everywhere.

Prof. George Fellows, of Indiana, says: "Most histories of the world are dreary compilations. This work, however, is clear, interesting and accurate."

Ex Vice-Pres. Stevenson says: "It is a complete record of the human race and should find a place in every Library."

E. Benjamin Andrews, Chancellor of the University of Nebraska, says: "Its educational value in the home is sure to be very great."

Rev. Frank W. Gunsaulus, of Chicago, says: "These volumes will be of immense service in stimulating history study in our country. It is a work of real genius."

Prof. Dabney, of Virginia, says: "Southern readers will be gratified at the impartial spirit in which the war for Southern independence is treated."

The St. Louis Globe Democrat says: "This work invests the study of History with a new charm that will be felt by both young and old."

NEVER BEFORE in the annals of the publishing business have we seen such a bargain. We do not hesitate to recommend this offer to every reader of this paper; indeed we believe every family should own a standard World History, for by knowing how other countries than ours are governed it gives us a better knowledge and higher appreciation of our own system of government and makes us better citizens.

We will be glad to give you an opportunity to see for yourself and make your own decision after you have seen the beautiful binding, the magnificent illustrations and have read parts of this great History of man on earth. Then you can decide. Should you not wish to keep the work you will notify us and we will have it returned at our expense.

The illustration of the books given here does not do them justice; you must see them to realize what they are. You assume no obligation to us or any one else by making this request, you simply **ask for a free examination** in your own home without paying any one anything, and remember you can send the books back at our expense, and remember, too, this bankrupt rock-bottom price of $28.50 for this $60.00 Library has been made possible only on account of the failure of the Union Book Company, thus necessitating a receiver's sale at a price which barely covers the cost of the paper and binding.

MAIL THE COUPON

15 Massive Volumes

Each volume 7 inches wide and 10 inches high; weight, boxed, nearly

75 lbs.

Here is Our Offer: Once more we wish to make our offer perfectly clear. Just write your name and address on the coupon, cut out and send to us and we will have this Library sent to you for free examination in your own home for an entire week. No mere description will do this History justice. You must see the volumes—the complete set, the beautiful binding, paper and illustrations; the large new type and read parts of the work itself. Then if you don't want it just notify us and we will send for the books at our expense. To own this work costs you only 50c down and $2.00 per month for 14 months—no more—and remember you get a regular $60.00 set of books for only $28.50 on easy terms or cash, if desired. This is our rock-bottom bankrupt price and the greatest book bargain ever offered to the readers of this paper. Use a postal or letter if you wish, but the coupon will do. **Send us no money.**

Address American Underwriters Corporation, Dept 235 , 240 Wabash Av., Chicago
We employ no agents. We send the books—not misleading maple pages—MAIL THE COUPON.

American Underwriters Corp'n, Dept. 235 , 240 Wabash Av. Chicago
— CUT OR TEAR ON THIS LINE —

Without expense or obligation, I would like to examine a set of the new Library of Universal History in my home free for a week. If satisfactory, will keep and pay your special price, otherwise books to be returned at your expense.

Cabbage Aphis.

I would like to ask if there is a sure method of keeping cabbage free from lice, one that can be applied without more trouble and expense than the cabbage is worth.—C. E. H., Holtville, Calif.

As the writer of the above underscores the word sure in his letter, we assume he wants to know very definitely. We might positively answer in the affirmative had he not added as a last suggestion that it must be a remedy that is to be applied without more trouble and expense than the cabbage is worth. The cabbage aphis is exceedingly troublesome once it is established in a community as it is over the entire Imperial valley. It is unfortunate that ranchers have not made an attempt to prevent this pest from securing a foot-hold in that section, for it has succeeded wonderfully in reproducing itself and has become a serious pest. The recent demonstration train carried with it and left in that section quantities of the little lady bug which will probably aid in keeping down the pest there this season. Mr. Ehrhorn's suggestion given to Imperial Valley farmers were practically these: Be sure the plants are grown in a bed so protected from the aphis by the use of cheese cloth or other protection that no aphis can get on the plants to be set, then remove all growth near where they are planted which may harbor the pest, allow no weeds to grow and the moment you notice a plant infected, either spray with kerosene emulsion or burn at once. Aphis increases rapidly and every family destroyed means a saving of millions of young within the next few days. At the time of marketing the old crop burn, or bury very deeply, any plants which may be left so that the millions of aphis will not be left to populate the field at planting of the next crop. If this is done and the fields left bare during the summer it should be clear of aphis next fall. The only absolutely sure protection would be to grow your cabbage in a glass case.

Protecting Apricots from Frost.

My Apricot orchard of 150 acres is loaded with bloom and promises a good crop. Several years ago there was promise for a good crop until April 1st, until a cold rain followed by cold west winds during the day and night breeze from the mountains brought us killing frost for ten consecutive nights. I did not have any crop at all. Are "Briquettes" made from crude oil, shavings ,etc., a sure protection from frost and how is crude oil burned in pots?—A. E., Moorepark.

Protection of a large tract of land as mentioned above would require extensive preparation and we doubt if it could be done in time to operate this year. The Griffith-Smudge Fuel Company, Los Angeles, or the Frost Prevention Company of Fresno can give you information in this matter. The Griffith Company use crude oil and shavings and manufacture a fuel which gives better results in a stove manufactured by the same company. We think the Fresno Company uses oil in its plan. If protection has to be given for ten nights it would be a question whether such protection would be profitable.

Pruning Eucalyptus.

Do the branches of Eucalyptus need to be cut off to a height of from four to five feet from the ground every year. I did that to my grove which is four years old and was told that I would ruin the trees.—J. A. S. S., San Jacinto.

If trees are to be grown for wood, or where it is desirable to have stocky trunks, they need not be trimmed up, for as long as the branches are growing it aids in making a stocky, larger trunk than if kept constantly cut off. The trimming of side branches causes the trunk to grow more spindling and is only done along walks as when in the way. In fact some prefer to top the trees so as to make side branches to grow more vigorously. On the other hand it is claimed that where these limbs are never trimmed and allowed to die, still hanging to the tree, that the wood continues to grow around the dead branches and makes a bad knot hole in lumber. For this reason it is advisable to remove all dead limbs.

Roselle Jelly.

At what stage should Roselle "pods" be picked for making jelly, is there any part of the bush used excepting the pods. What causes rhubarb to go to seed and how close should it be pulled.

We enjoy the Cultivator very much and draw straws to see who gets it first.—M. & S. Ritchey, Amador County.

The calyx or so-called pods are picked before the seed hardens, some cut the pod in two before using for jelly, others strip off the fiesy calyx and use it alone, as a rule, however, the whole, uncut pod is used in making jelly. This fleshy calyx and the gelatinous substance around the seeds are the only parts of the plant used. The delicious acid drink made from these calyxes should encourage its more extensive culture. The seeding of rhubarb is very perplexing and the only remedy is to cut as soon as the seed stalk starts. The plants vary greatly in this particular. Some never run to seed at all, those which are the most persistent are almost worthless for that reason.

Veterinary

Answers in this column by Dr. R. T. Whittlesey, are without charge. For immediate mail answer remit $1.00. In writing questions give full symptoms or particulars of injury of animal.

Capped Hock.

I have a young horse, unbroken, that has swelling on point of hock; the skin seems to be thickening; there is no soreness or lameness. I first noticed it several months ago, and blistered lightly several times, which seemed to reduce swelling somewhat, but doesn't remove it. What is trouble and treatment?—Subscriber, Paso Robles.

Your horse has what is called a capped hock; it does him no harm in any way but looks. It will probably never entirely disappear, and I know nothing better than what you have used. You might repeat it several times, giving the skin plenty of time to recover between blisters.—R. T. W.

DR. WHITTLESEY'S VETERINARY REMEDIES.

These are not ordinary mixtures but are from well tried formulas, used in an extensive practice in Southern California for nearly a quarter of a century. Dr. Whittlesey's Sulphur Arsenical Salve for deep fistulous or ordinary chronic, indolent sores such as, "Poll Evil," "Fistulas," "Quitters," "Thrush," "Scratches," "Warts," "Collar sores" or "Sit-fasts." $1.00 per package postpaid. Printed directions. Dr. Whittlesey's Antiseptic Healing Powder. Forms a coating over raw surfaces, excludes air, flies and floating germs. Makes a cheap and convenient dressing for the many sores that occur to stock on the ranch. $1 full pound can postpaid.

DR. R. T. WHITTLESEY.
Veterinary Hospital, 714 East Seventh St., Los Angeles, Cal.

Bees and Their Care

SOME MISAPPREHENSIONS CORRECTED.

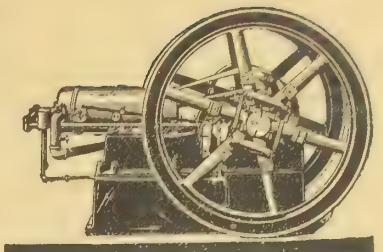
THE Cultivator recently quoted from an article in Gleanings in Bee Culture which criticised the proposed California law, or ammendment to it rather. Regarding that article Prof. Ralph Benton, in charge of Apiculture, University of California, writes:

"The main trend of this discussion is correct, but there are certain misapprehensions and interpretations that we desire to clear up in the minds of the beekeeping public. In the first place when attempts are made to discuss or interpret the California law or the amendment in question, it must be borne in mind that our law relates not only to foul brood but to all of the brood diseases of bees and also to the adult diseases of bees commonly and collectively called paralysis. Keeping this steadily in mind let us consider some of the questions raised in the discussion referred to. In the first place the statement is made that the amendment provides for a 'University Inspector of Foul Brood.' This is but a slight error in name, but we desire to correct it for the term so used is misleading. What the amendment does provide for is a State Supervising Inspector of Apiaries who shall be Apiarian Pathologist of the State Agricultural Experiment Station, an institution separate but closely connected with the University. Note that this officer is an 'Inspector of Apiaries' and not simply a foul brood inspector. This is true of all of our county inspectors under the present law; they are 'Inspectors of Apiaries' and as such inspect and treat for not only foul brood, but all of the other maladies of bees. As Apiarian Pathologist the State Supervising Inspector of Apiaries will conduct investigations in the diseases and other enemies of bees, and undoubtedly, ranking as an Instructor in the University, it will fall to him to conduct such courses of instruction as are given in the College of Agriculture in the diseases of bees.

"Now coming to the main point around which most of the discussion pro and con has centered. We refer to the section relating to the importation of queens into California. There are two things that must be remembered when discussing this section; firstly, the section in question relates to the importation of queens not only in ordinary mailing cages but also queens in 'nuclei' or 'swarm boxes'; and secondly that the whole law relates in all of its applications not only to foul brood but to all brood diseases and also to the adult diseases of bees or paralysis. The exact causes of certain of these diseases is not known, but there seems to be overwhelming evidence pointing to the fact that certain of these diseases known as pickled brood and paralysis are in some way directly connected in transmission and spread through the queens. Time and again have these diseases been introduced into apiaries previously free from disease through the agency of an importation of queens. Time and again have partial and in some instances in certain of these diseases a permanent cure resulted from requeening with fresh and uninfected stock the apiary so infected. When we refer to these diseases which in certain portions of the United States do not flourish and in many portions are but minor maladies, an adequate appreciation must be had by the beekeeping public of the virulence and the extent of the ravages of these same diseases as transplanted and permitted to flourish under California climatic and other conditions. In some localities so-called paralysis is much more dreaded than foul brood and rightly so if we are to judge from the havoc wrought by this baffling disease. The writer has been in apiaries in California in which all of the flight bees have been taken off and hive after hive so decimated in numbers that brood rearing operations were at a standstill for lack of bees and stores to proceed on. In passing down the rows of such an apiary, from a pint to two quarts or more of dead bees could be scraped up in a pile in front of each colony and hardly a place to step without crushing a struggling and diseased bee. If foul brood is an insidious disease in that it cuts off the supply of young bees, paralysis is just as insidious as far as practical returns are concerned in that it takes off all the flight or working bees. So much for the basis upon which the beekeepers of California have seen fit to include in their proposed law a section relative to the importation of not only bees, but specifically queens as well.

"Now a few words in regard to the possible interpretation of the law. The proposed measure is very clear and definite in its statement. There is nothing in it relative to the inspection of queens either at the postoffice or at an express office. There is nothing in it in fact binding an immediate inspection of queens upon their arrival by the inspector unless the inspector so desires to rule. What the section in question does provide is first that all queens introduced into the State of California or from one county into another county within the State without a clean bill of health are so introduced at the risk of the consignee. If the consignee does not wish his property endangered and to make himself liable for the importation of uncertified bees, immediately upon the arrival of such a consignment of bees, he is required to notify the inspector of apiaries holding such queens subject to his orders. With the sanction of the inspector the queens may then be introduced into the apiaries of the consignee and kept under observation for a period of not less than sixty days at the end of which period if no disease has developed the queens may be pronounced free from disease and then and only then lawfully introduced. This in no way debars the sending of queens into California by any eastern breeder and as Mr. Root has repeatedly asserted works no hardship there, as Mr. Pryal anticipated might result to Eastern shippers of queens. And, further, California bee keepers do not, as Mr. Root anticipates, feel it a hardship at their end of the line since it is with the California beekeepers that the proposed measure emanated and they have been supporting it with an overwhelming majority, quite unanimously except in a few quarters. As we have repeatedly pointed out, the real burden would lie

(Continued on Page 362.)



A RELIABLE WATER SUPPLY FOR IRRIGATION

AFTER preparing the ground, sowing the seed and getting the crop well started, your greatest concern is for a reliable water supply.

You *must* have water to irrigate in season. Your crop may be ruined in a single day for the want of it.

You have a dependable supply of water in the form of low lying lakes, ponds and reservoirs. The problem is to raise this water so you can apply it to the land.

Do you know that you can raise such water and make it available for irrigating all your lands by means of the powerful I.H.C. gasoline engines?

They will not only pump water for you in large quantities, but they do it economically. It costs practically nothing to keep an I. H. C. engine in repairs, and the expense of operating it is a very small item compared to the value of the crops you can raise.

An I. H. C. engine as the basis of your irrigating plant makes you master of the situation. You are independent of the ditch and ditch officers. You have a water supply that is all your own. You can start your engine any time and apply water to your land whenever the crops require it.

Keep an I. H. C. engine supplied with gasoline and it runs dependably, hour after hour, requiring but very little attention. You need return to the engine only occasionally, so you are free to spend practically all your time handling the water in the field.

One of the advantages in purchasing an I. H. C. engine is that the engine can be used for many other purposes besides pumping. It is a general all-round farm engine—an absolutely reliable source of cheap power for operating the grindstone, churn, fanning mill, feed grinder, separator, bone cutter, washing machine, etc. I. H. C. engines are made in many styles and sizes, so that you will be able to find just the engine you want. There are

I. H. C. Vertical Engines—made in 2, 3 and 25-horse-power.
Horizontal (portable and stationary)—in 4, 6, 8, 10, 12, 15 and 20-horse-power.
Gasoline Tractors—in 12, 15 and 20-horse-power.
Famous Air-Cooled Engines—in 1 and 2-horse-power.
Spraying and Sawing Outfits in various styles and sizes.

Call on the International local agent handling I. H. C. engines. He will supply you with catalogs and full particulars. Or, if you prefer, write to nearest branch house.

SOME MISAPPREHENSIONS.

(Continued from Page 361.)

with the inspectors of apiaries increasing their duties, but the California beekeeping public seems willing to increase this line of work in its united effort to restrict and eradicate bee diseases locally costing the honey industry annually in the neighborhood of $250,000.00 to $300,000.00. If an aggressive campaign is to be carried on, all possible sources of infection must be guarded, and the great advantage accruing from a system of complete inspection including queens is being able to locate definitely if possible the sources of constant reinfection and concentrate a united effort upon these sources and so solve the problem the immensity of which relatively speaking few beekeepers realize. We believe that suppositions or possible interpretations of the law are endless and in general lead to nothing and are more of the opinion of Mr. Pryal that the law framed in the best interest of all should pass and if in interpretation it is ineffectual it can then be changed and strengthened to suit the situations that may arise in the future."

MUTUAL INSURANCE.

The California Mutual Live Stock Insurance Association of California, with its home office at Oakland, is the only institution of the kind organized under the laws of the state with its home office in the state.

They insure live stock against death from disease, fire, lightning, tornado, cyclones and every casualty; also through accident which may necessitate the death of any animal.

Losses are paid promptly without discount and without unnecessary delay.

They have a guaranty deposit under the control of the State Treasurer for the protection of their members and policy holders.

There is $100 of values lost to farmers by death of stock, by disease and accident, where $1 is lost by fire.

They have no dividends or profits paid to idle office holders.

The business of the Association is conducted as economically as is consistent with good management, and the earnings are divided among the policy holders.

This is an age of Mutual Insurance, and it is true the cheapest and strongest companies in the United States today are composed of and managed by the policy holders, who are farmers and stockmen, as has been demonstrated in the East and as this company is demonstrating in California.

For further information see their advertisement in this and other issues, or address for circulars, M. L. Wright, President and General Manager, Bacon Building, Oakland, Cal.

POULTRY.

THE GOSPEL OF LABOR.

The legend of Felix is ended, the toiling of Felix is done;
The Master has paid him his wages, the goal of his journey is won;
He runs, but he never is idle; a thousand years pass as a day,
In the glad surprise of that paradise where work is sweeter than play.

But I think the King of that country comes out from his tireless host,
And walks in the world of the weary, as if He loved it the most;
For here in the dusty confusion, with eyes that are heavy and dim,
He meets again the laboring men who are looking and longing for Him.

He cancels the curse of Eden, and brings them a blessing instead;
Blessed are they that labor, for Jesus partakes of their bread.
He puts His hand to their burdens, He enters their homes at night,
Who does his best shall have as a guest the Master of life and of light.

And courage will come with His presence, and patience return with His touch,
And manifold sins be forgiven to those who love Him much;
And the cries of envy and anger will change to the songs of cheer,
For the toiling age will forget its rage when the Prince of Peace draws near.

This is the gospel of labor—ring it, ye bells of the kirk—
The Lord of Love came down from above to live with the men who work.
This is the rose that He planted, here in the thorn-cursed soil,
Heaven is blest with perfect rest, but the blessing of Earth is toil.

—Henry Van Dyke.

SHE KNEW A WAY.

"STRELLICK doesn't dare say his soul's his own," said the married man. "That's a fact, too. I understand that his wife made him join the church."

"A good thing for him," commented the man's wife.

"I don't deny it," said the married man, "buf it's pretty tough not to be able to draw a long breath without asking your wife's permission."

"Are you talking about his inhaling cigarette smoke?" asked the man's wife. "If you are, I think it was just as well that she stopped it. You know that you've been feeling a great deal better since you stopped smoking."

"Pooh!" said the married man. "I don't notice a particle of difference. I wasn't feeling badly, anyway."

"You're looking a great deal better."

"Nonsense!" said the married man. "I don't really think that an occasional cigar or pipe hurts a man. It's only when it's carried to excess that it's injurious. I'm thinking seriously of beginning again."

"Of course, as you say, you know best how you feel," said his wife. "You know that I wouldn't wish to deprive you of any comfort or dictate to you in any way."

"I should hope you wouldn't," said the married man. "You'd be rather badly fooled if you did. I'm not Strellick."

"I'm very glad you're not, dear," said his wife. "I should be sorry to have my husband afraid to say his soul was his own. It's your soul, my dear, and it's your own brain and body that you are hurting—and your own heart. You used to tell me that it was my heart, but that was when you were in love with me."

"Who's been telling you that I'm not in love with you now?" asked the man.

His wife smiled sadly. "Well, if you are bound to kill yourself I haven't any right to say anything," she sighed. "But you are looking better, dear, I assure you. You have a better color and your eyes are brighter and your face fuller than they used to be when you were smoking so much."

"What are you talking about?" exclaimed the married man. "I never smoked so much. I was always a moderate smoker. It wasn't because I was feeling any effect from it that I stopped. I just did it to please you. Because I wanted to please you, I said I would try it for a little while. If you had been like Mrs. Strellick and thrown my cigars into the furnace you wouldn't have got me to stop, I promise you that. Honest, how a man can let a woman boss him the way Strellick does is beyond me."

"I think she ought to be ashamed of herself," said the man's wife. "I call it unwomanly. Still, if I had a husband like Mr. Strellick there's no telling. I'm pretty well satisfied with my own, though."

"That's good," said the man in a gratified tone. "I was only thinking of a cigar, say, after dinner or—"

"You know you wouldn't be satisfied to confine yourself to that," said the man's wife.

"Do you mean to say I havn't got any self-control?"

"You know I don't. I know you better than that. If you could keep from smoking at all as long as you have I know you've self-control to smoke one a day, or to keep on without ever smoking. I was telling Mrs. Ritchie the other day that there wasn't any danger of your relapsing; you had too much strength of mind. She was saying that it wouldn't last. She noticed, too, how much better you were looking. She said she believed you grew handsomer all the time. I felt a little bit jealous. It was so nice, though, not to have you all smelly of tobacco and to know that you did it to please me, and that your appetite was so much better, and your nerves. Still, I'm not going to be selfish. If you don't want to please me any longer and would sooner spend your evenings in the basement—"

"Oh, I'm not particular about smoking," said the married man. "It would probably make me sick if I began again, anyhow."—Chicago Daily News

About the House

IN planning the meals, see that one kind of food supplements another. with a heavy meat course, serve a green salad, and one of the lighter desserts—fruit either cooked or uncooked, a delicate pudding or a fruit pie, leaving the hearty soups, the rich puddings, and mince pies for the days when fish or the lighter meat dishes are on the table.

Are you one of the lucky—or perhaps I should say skillful cooks, who never burn a cake or pie, never have anything "stick" to the kettle in which it is cooked? If you are one of these happy persons just skip the following paragraph clipped from an exchange.

When the boiling vegetable has

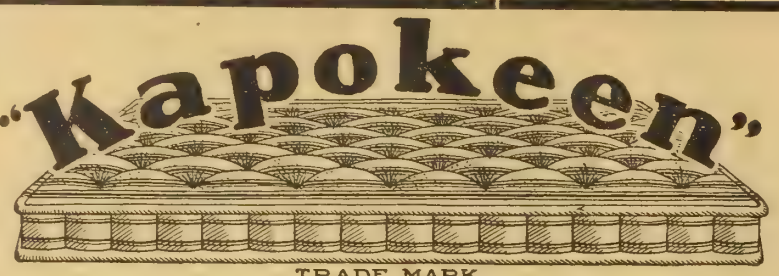
"Kapokeen"



TRADE MARK

The Mattress of Quality

In introducing our Kapokeen Mattress to the readers of The Cultivator, we are taking the first steps toward establishing a National reputation and market for an article, which, on account of its many advantages, has gained a pre-eminent position in its own vicinity.

"Kapokeen" is made from the Kapok or silk floss obtained from the bean of the Eriodendren tree, grown on the island of Java. It is prepared by our own patented process, which removes every particle of seed and preserves in full the resiliency of the natural fibre.

The mattress is made in our own factory where every precaution has been taken to insure absolutely hygienic conditions, by skilled workmen using only the best quality of materials throughout.

NOTE THESE POINTS.

Kapokeen can be "made over" in exactly the same manner as hair.

Kapokeen is sun dried, sun cured, and free from chemicals or other foreign substances.

Kapokeen, no matter how long it has been in use, by being placed for two hours in the sun, will expand and become as resilient as a new mattress.

Price No. 1 Kapokeen Mattress, 4-4 size, 5 1-2 inch box, Imperial edge satin ticking **$15.00**

Three-Quarter Size, $12.50 Single, $10.50

Kapokeen Mattreses are made only by

John Breuner Co

A postal will bring you a little booklet describing this mattress

Angle Lamp

The Light That Never Fails

Thousands in use all over the country. A good light is the greatest pleasure and the first necessity of every home.

The only lamp on the market that is sold under an absolute guarantee.

Remember, the light from Kerosene is the light science has agreed upon as being the purest and best, because it is soft and mellow and restful to the eyes.

Here are a few of The Angle Lamp Merits:

NO UNDER SHADOW. NO SMOKE, NO ODOR, LITTLE HEAT.

GREAT ECONOMY—COST LESS TO BURN than an ordinary lamp. As easy to operate as gas or electricity, and better than either. ABSOLUTELY SAFE under all conditions. Lighted and extinguished like gas. Burned HIGH or LOW like GAS without a trace of odor. And a BRILLIANT, soft, steady, shadowless light—but this you will have to see to appreciate.

The lamp as shown in cut burns 22 hours on 3 quarts of oil.

caught, don't try to pry it out of the saucepan and take all the burnt taste with it, but, rather, plunge the outside of the saucepan into cold water a few moments; and when you loosen the vegetables carefully with a spoon the hardened burnt portion will remain in the pan.

When the small cakes in gem pans have done just a moment too long and seem inclined to stick to the pans, try the same plan, only less strenuously. Hold the under sides of these hot little pans against a wet tea towel, and the cakes will loosen at once.

After greasing your cake tins with lard and before pouring in the cake batter dredge the bottom of the tins with flour, shaking out all that does not stick evenly to the lard. Cake batter poured in on this dry flour will rarely stick to the pan after it is baked. Wet the inside of china or tin moulds with white of the egg before pouring in gelatine, cranberry or blanc mange, and the hardened dessert will not stick when you are ready to dislodge it.

To make a quick short cake split hot baking-powder biscuits, and fill with preserves, any kind you like, and serve with cream or a good pudding sauce. If you have no cream and no time to make a sauce, take sweet milk, add sugar and a little vanilla or nutmeg and serve with the short-cake. It is very good.

An old housekeeper says that if scorched milk be poured into an earthen ware bowl and the bowl placed in cold water, the scorched taste will disappear by the time the milk is cold.

Man's ideas for the proper training of daughters were very much the same when this old rhyme was written as they are now:

"I tell thee, wife, we'll have our daughter bred
In bookerie, cookerie, needle, thimble, thread,
To be expert and ready at her prayers,
That God may help her to avoid the Devil's snares.
Let her be taught to shun deluding,
To roast, to toast, to make a pudding,
To knit, to spin, to sew, to make, to mend,
To rub, to scrub, to earn, and not to spend."

—Elbepe.

THE ART OF FOLDING NAPKINS.

The table napkin, or serviette, which is now almost indispensable as a table appointment, was, until the fifteenth century, only used for children; prior to that period the ends of tablecloths served as a sort of napkin. The edges of the tablecloths then nearly reached the floor. It was then considered the correct thing for grown up people to wipe their lips and hands on the long folds of the tablecloths. When napkins were first introduced they were not folded in an artistic manner, as is the case nowadays. For a time the artistic folding of serviettes went out of fashion, but within the past few months the custom has been revived, and it has again become the fashion to place a neatly folded napkin on the cover of each diner.

Ancient books on the subject of table etiquette state that they were first placed over the left shoulder of the diners, so that the ends could be raised to the mouth when needed. Later they were laid across the left arm, and still later, hanging or tying them round the neck, in bib like style, was accepted as the proper position.

The French take the credit of having first introduced the art of folding table napkins. The fashion of folding serviettes for table was adopted in this country. The French people of that early period were rather extravagant in the use of napkins, for, it is said, not only for every meal, but actually with every course the napkins were changed. It was then the custom, in addition to folding them in the most artistic manner, to perfume them with scents, such as rosewater and lavender, or with flowers bearing a pleasant fragrance.

Some exceedingly pretty and ingenious designs have from time to time been introduced, so that folding napkins has long taken rank among the small fine arts. The satin like damask, by means of many folds, turns and twists, can be made into the shape of fans, ships and boats, caps, flowers, birds and fanciful figures of all kinds. Needless to say, it requires both patience and practice to enable one to fold serviettes into such ornamental shapes.

First lay the serviette quite open upon the table, bring down the top

edge to the center and then do the same with the bottom end, and press down the creases firmly. This must then be turned completely over, care being taken that the two folds are not disarranged. Carry up the bottom edge until it rests upon the top—really folding the whole in half—and a long rectangular figure, consisting of four equal folds of linen, is formed. This must then be plaited from the center to each end. When the plaiting is completed the upper edge of both sides should be vandyked by slipping the first between the two folds and pulling the linen down between the plaits, at the same time pressing the two plaits on each side together. This done, the serviette is a single-plaited "fan," vandyked on both sides, but by carefully separating the two folds at the top by means of both hands, and pulling them gently apart, plait by plait, the "double fan" commences to take shape, and the plaits only require to be pressed together at the lower edge and placed in a wine glass, for the fold to be ready for table.—Food and Cookery, London.

HOUSEKEEPING ON A BUSINESS-LIKE BASIS.

It seems to me quite desirable that housekeeping should be placed upon a businesslike basis. More than half the earnings of the average wage earner are spent for food alone. In spite of this, very few people know how to select their food so as to get the best for the least cost. Years ago the housekeeper planned the spending of money very wisely; but stern necessity had taught her how to do it. Many housekeepers love bargains, and so it comes that sometimes cheap goods are bought. The old proverb that "the best is always the cheapest in the end," is always true. Many women think they are quite businesslike if they save a cent; for instance, if the original cost was one dollar, they think it is a bargain at ninety-eight or ninety-nine cents. Often women will waste time and energy running from one store to another in order to save five cents on the purchasing price. It is the same in food, and women will buy cheap food and then pay large fees for medical attendance. Sickness is not always sent by providence, but is sometimes the direct result of unwise administration of the household affairs.

Every housekeeper should keep an account. Many women do not have five cents they can call their own; while many a man has been ruined by allowing his wife to have full control of the money. I know there is blame on both sides.

Housekeepers should know something of housekeeping before they enter the business of making a home. If you can do your work a little bit better than someone else, that work is always a source of delight to you, and it matters not what the work is. Every young woman who intends to marry should make it her business to master some of the problems of housekeeping.

We cannot all be great singers, or great artists, but if we do our work, even if it be scrubbing floors, better than someone else does it. it is always a source of more or less pleasure, and it is respectable.

This subect is one that is much more important than the general public think.

The getting of the income, man's work, is a subject of a great deal of importance; while the spending of the income, woman's work, receives very little attention. It is true that the man provides the income; also true that the woman spends it. Comfort, ease, and happiness depend as much upon the spending of the money as upon earning it.

To put housekeeping on a business basis we must know the real importance of the subject so that we may respect it.—Mary F. Rausch, Colorado Agricultural College.

IRONING DAY HINTS.

Skilful laundresses know that to iron a starched article when too dry results in breaking the threads of linen, which in a short time makes the frayed edge, or the hole. They also know that hot water dampens the clothes more evenly than cold, and makes the garments more quickly ready for the iron.

A sprinkler, which is much better than the hand, can be bought at the house-furnishing shops. It consists of a rubber bulb with a rose sprinkler attached—just like those the florist uses for watering the plants in his window.

When ironing stocks for the neck or embroidered linen collars iron them on a thick towel which has been folded three or four times and laid on the board. Stocks ironed in this manner will appear like new, and if you iron the embroidered linen collars on the wrong side on this folded towel the embroidery pattern will stand out in bold relief.

The cloth on the ironing board can be kept clean when not in use, by slipping the board into a cover of muslin or calico, made like a big pillow case with a draw-string.

TO CLEAN VELVET.

Velvet may be cleaned by soaking it for several hours in a covered jar of gasoline. Stir it around frequently with a stick and then rinse in clean gasoline, handling it as little as possible. Hang the velvet in the air to dry.

Want a Telephone?

If you do you can get it. If you are anxious to get into closer touch with your friends, with the family doctor, with the store, with the post office, or with the cotton buyer, you can do it with a telephone at hand. If you want to make the farm a more livable place, if you want to protect your home, you can do it by installing a telephone.

If you will cut out this advertisement, write your name and address on the margin and mail it to-day to our nearest house, we will send you at once a copy of our Free Bulletin No. 71 on

"How to Build Rural Telephone Lines"

This Bulletin explains clearly how a rural telephone system is built and operated, and it also contains full information as to costs.

In a Farmer's Mutual Company a few day's labor and a cash investment of about $25. per subscriber, will purchase all material and build an absolutely standard system.

A Rural Telephone is an investment, not an expense. The telephone which enables you to sell ten bales of cotton at ½ cent per pound more than the traveling buyer offers you, has paid for its entire cost. If you have some hay down all ready to go in, it is worth something to have a telephone with which to call on Neighbor Smith "for a lift" before the storm breaks.

The Rural Telephone pays for itself each year and we have brought the initial cost within the reach of every farmer. Present prices are especially favorable and thousands of Farmers' Mutual Companies are now organizing so as to build their lines this Spring. **Write us to-day.**

Hay.

Scott and Magner say under date of March 20: Arrivals during the past week have amounted to 3931 tons. It is most remarkable that notwithstanding the heavy arrivals during the last two or three weeks, prices upon our market have not only not declined, but have advanced somewhat. The demand has been strong and has readily absorbed everything coming in. Judging from this, and from the active demands upon today's and yesterday's market, it looks as though our market might take still another step in advance, and prices increase still further.

It has been the opinion of the local dealers that our market would not stand anything like the heavy supply that has been coming in without dropping off somewhat, or at least becoming weak, but it is the common impression now, judging from the way in which the demand has kept up that our market will not only maintain its present strength, but will probably advance at least a dolar a ton more in the near future.

There seems to be quite a bit of life in the export trade, and would undoubtdly be much more if the hay could be spared from local consumption. Alfalfa continues selling at high figures, but the season on this is drawing to a close; green feed and the approach of new crops will completely demoralize the alfalfa market in a very short time.

Citrus Market

LOS ANGELES, March 24, 1908.

A material betterment of the market conditions of oranges has occurred during the week. This is possibly due to favorable weather conditions, but in part it may be credited to the advertising campaign which is still under way. Eastern grocers are entering into the spirit of the orange movement and are offering oranges alongside of apples at the same price or usually lower than the apples. This novel method of selling oranges aids in attracting attention and undoubtedly the sales are much greater. The feeling is that it will aid in lifting the orange out of the luxury class and place it with the necessities in the eyes of the consumer.

Lemons are fully as good as they have been and only need the stimulus of some hot weather to make a keen demand and give an upward trend to prices.

Shipments.

Shipments of oranges to date this year total 11,563 cars, lemons 1,848; or a total of citrus shipments for the season of 13,411 cars.

NEW YORK, March 22.—Forty-nine cars oranges and six cars lemons sold. Market is active on navels when of good quality. Market is dull on ordinary grade lemons. Weather clear, cool favorable.

All harness leather needs an occasional oiling and blacking, and

EUREKA Harness Oil

is best for the purpose. There is no acid quality about it and it cannot become rancid. "Eureka" penetrates deep into the leather and *stays there* to resist the rotting effects of wet and weather. Use Eureka Harness Oil.

STANDARD OIL COMPANY,

FIRELESS BROODERS.

Coulson Co., of Petaluma, Cal., who now handle the entire output of Ward's Fireless Brooders, made by the A. P. Ward Brooder Co., of Calistoga, Cal., report a heavy demand for these brooders. One recent telegraph order called for two dozen large sized brooders for Owen River Land & Cattle Co., who have tried them out and find they fill the bill.

They report shipment to practically all parts of the Pacific Coast, including Idaho, Utah, Washington, Oregon, Nevada and Arizona.

It looks as if the "Fireless" had come to stay, and it certainly is a time and money-saver for the poultrymen.

MAKING $118.93 PROFIT PER COW IN ONE YEAR.

The story of S. W. Coleman of Sedalia, Mo., is an inspiring one for every farmer and dairyman. It shows what one man can do with little capital on a few acres by right methods. Mr. Coleman made a clear profit of $832.50 from seven cows in one year on only ten acres. Think of it, only ten acres and seven cows! That is a profit of $118.93 per cow a year or $83.25 per acre.

This successful dairyman is just as expert at butter making as he is in increasing milk flow. For years he has won first prize on butter at the Missouri State Fair and elsewhere. He uses a United States Cream Separator to get all the butterfat out of his milk and states that it greatly aided him in improving his methods of buttermaking as well as saving him hundreds of dollars in cream he otherwise would have lost. For ten years he used one United States Cream Separator without having to spend a cent for repairs.

The United States Separator will do as much for you. Begin to save now by writing to the Vermont Farm Machine Co., Bellows Falls, Vt., for their Catalogue No. 20 which tells all about the United States Cream Separator. This book is handsomely illustrated, clearly and entertainingly written, and above all, it tells you how to make money.

Mixed The Parts Ran Perfectly

YOU like to know that your cream separator is so simple and finely made that, if necessary, you can order any part and be sure it will fit perfectly.

We insist upon exactness for every part of every Sharples Tubular cream separator.

Constant tests keep the making of Tubular parts perfect. One test, recently made, was both unusual and positive proof of Tubular exactness.

We took twenty Tubular Cream Separators, at random, from our immense warerooms. They were already boxed for shipment. We had those twenty cases opened. We had those twenty Tubulars taken entirely apart. Every part was taken from the frames and separated into single pieces, down to the smallest screw and spring. ***All the separate unmarked pieces, from those twenty Tubulars, were mixed together in a single heap.*** Then we had those twenty Tubulars put together again.

Every part that went into them was fished, at random, out of that mixed-up pile. Just one chance in twenty that any piece was put back into the machine from which it had been taken.

Then we sent those twenty Tubulars to our big testing room, where every Tubular is given an actual running test, and had ***every one of the twenty tested. Every one of them ran perfectly*** showing that every part was perfect and interchangeable.

Tubular perfection, simplicity and superiority have made Tubulars so popular, all over the world, that the Tubular factory is the largest and finest separator works in the world. We also have branch factories in Canada and Germany.

Tubular sales for 1908 were way ahead of 1907—out of sight of most, if not all, competitors combined. The plumb bob, and other improvements on our 1909 Tubular "A" will make 1909 better yet. Write for catalog No. 260, fully describing the finest cream separator money can buy.

The supply can is set low and on the side of Sharples Separators. It is easy to fill, always steady, and need not be lifted off to remove either the milk and cream covers or the bowl from the machine. The supply cans on all other separators are directly over the bowls and must be lifted off before bowls can be removed from such machines, which is doubly unhandy if the can is full.

What Our Subscribers Think of Us

Read what a few subscribers say as to the value of the CULTIVATOR as a farm, stock, fruit and poultry paper:

Mission Valley, Cal., Feb. 1, 1909.
Enclosed find P. O. money order of $1.00 for my subscription for this year. I am well pleased with your paper and wish you all the success that your efforts deserve. I appreciate your plan of indexing the previous numbers. It saves the readers a lot of time and no small amount of annoyance in going over the file. I have filed all my Cultivators for the past year except two that I have either mislead or lost. One of them had a breeding chart that I would like to have, and if not too much trouble for you to print again, I should feel obliged to you for doing so. Respectfully yours, J. T. J.

Santa Barbara, Cal., Feb. 3, 1908.
I again beg leave to ask you to change my paper from 119 E. Ortego street, Santa Barbara, to Lompoc. My subscription was paid in through the Graham Drug Co., at Lompoc. Am sorry to trouble you more but I am required to change, therefore, your paper must follow. Yours very truly, G. O.

San Dimas, Cal., Feb. 16, 1909.
This check pays for Cultivator one year for J. W. S., Charter Oak, Cal. This is the third new subscriber I have sent you within a year. Don't you think you ought to mark my date up about six months. Please change address from Charter Oak to San Dimas, and oblige, Yours truly H. E. W.

Claremont, Cal., Feb. 8, 1909.
Enclosed find check for $1.00 to renew my subscription to the Cultivator. To an amateur farmer or dairyman, or a tenderfoot, it is indispensable. Thanking you for all advice given me in the past, I am going to trouble you again with some questions, which you will find on another sheet. Yours truly, W. P. R.

Stonyford, California.
I enclose money order for the renewal of your paper and also the price of subscription for my neighbor, Mr. F. H. I will say I prize the Cultivator very highly and shall always speak a good word for it to all neighbors wishing a valuable farm journal. G. D. L.

Cupertino, Cal., Feb. 2, 1909.
Cultivator of January 28th to hand, but I did not receive the previous issue. It is the first time I have ever been overlooked. I enjoy your journal too much to miss a number so will you kindly forward me the missing one and oblige, Yours sincerely, C. H. S.

Folsom, California.
Enclosed find postal order for $2.00, which will pay for the past year and the one coming. I consider the paper the best that I have ever read and that is a good many. I would not be without the Cultivator for twice the price. C. W.

Yettem, Cal., Jan. 13, 1909.
Please change the address of the copy of your paper addressed to D. H. T., Laton, Cal., to D. H. T., Yettem, Cal., and oblige. Every farmer needs your paper as your suggestions are good and practical in all branches, of farming. D. H. E.

Watsonville, California.
I am very much pleased with the Cultivator. It is very instructive. I can't do without it. C. T.

Vacaville, Cal., Feb. 7, 1909.
I am enclosing payment for one additional yearly subscription to your paper. I find your paper of great value. Yours very truly, C. R. McB.

Holtville, Cal., Feb. 11, 1909.
Enclosed find check for $1.00 for which please send me the California Cultivator, renewal for the year 1909. A ranchman cannot invest a dollar any where to better advantage than by subscribing for the Cultivator. Yours for success, E. W. B.

Wahtoke, Cal., Feb. 2, 1909.
After reading several copies of your paper sent to one of your subscribers, who also highly recommends the paper, I wish also to become a subscriber and will find herewith $1.00 for one year's subscription, and oblige, Yours truly, T. B. H.

San Martin, California.
Enclosed please find money order for $1.00 for continuance of your valuable paper. Kindly accept thanks for continuing after date of expiration. O. N.

Escondido, Cal., Jan. 4, 1909.
Your collector has not been here this year so I enclose $2.00 for current year and one year ahead from 1908 to 1910. The Cultivator is all right. Very truly yours, C. H. W.

Pomona, Cal. Feb. 6, 1909.
Please find check for $2.00 to settle account and extend. Respectfully, W. T. A.
P. S. A mighty good paper for the orange growers.

Loomis, Cal., Feb. 12, 1909.
Enclosed find money order for four ($4.00) dollars to renew the subscriptions of J. H. N. and R. M. N., two dollars each, to Loomis. We like the paper very much and would miss its visits to our house. Yours truly, R. M. N.

Santa Rosa, Cal., Feb. 3, 1909.
Enclosed find order for two dollars for subscription to your valuable publication. Thanking you for courtesy extended as well as for useful information received, I remain, Yours truly, C. T. M.

Turlock, Cal., Feb. 18, 1909.
Enclosed find $1.00. Please credit us one more year for the Cultivator. You are getting out an excellent farm paper which every farmer should take. Yours for improved methods in farming, E. Bros.

Douglas, Ariz., Feb. 1, 1909.
Can you send me the "Cultivator" for August 27th, 1908? I appreciate the "Cultivator" so much that I do not like to lose a single number. I enclose you 5c. Sincerely yours, H. C.

Kingsburg, Cal., Feb. 5, 1909.
Enclosed please find one dollar in money order for sending me your paper, the California Cultivator for another year. I like your paper very much. It is a good help to a new beginner. Yours truly, O. B.

Sarita, Texas, Feb. 5, 1909.
I failed to receive the January 28th issue of the Cultivator. Will you please send me another copy as I can't afford to miss a single number. Yours truly, J. H. A.

Biggs, Cal., March 14, 1909.
We missed copy of the Cultivator, March 4th. Would like very much to get one of that date, if possible, as we wish to keep them every one. J. & P.

California Cultivator

Date Growing in Southern California

A Valuable Product if the Tree Will Make Good and Bear in This State. Palms Now Growing at Several Points in Southern California and Arizona

WHILE at Mecca recently we made a short visit to the experimental date farm. We were not impressed with the manner in which the farm, or garden, whichever it may be called, is cared for. The place had a most unthrifty look, and the palms which were living did not have the appearance of strong, healthy growth. Sure it is, if such culture will grow a profitable date orchard, a thrifty farmer will do well. A gentleman who lived near the place, however, informed us that at the time of the rise of the Salton Sea when it was thought the farm might be inundated, some of the plants were moved to higher ground and that the appropriation for the one farm is now divided and spread over the two places.

The Salton Sea is but little more than a half a mile away.

At the time of the visit, there were only a couple of small bunches of fruit, and neither of those had any seed, owing to the pollen which was used on the blossoms having no life. The fruit was consequently of no value.

The question yet to be solved is, will date culture become a commercial factor in the hotter, drier sections of California. We hope it will, and think the experiment worthy greater effort than is apparently yet made at the Mecca station.

Some points which may have a general interest to our readers are taken from an article written by Prof. Silas C. Mason, Arboriculturist, Plant Life History Investigations, Department of Agriculture and read at the State Fruit Growers' Convention at Riverside last year.

Culture and Management.

In its cultural requirements the date palm is the most unique and interesting, perhaps of any tree yet introduced into this country.

Dioecious in character, except in the case of occasional rare examples, that is, bearing the male and female flowers on separate trees, a miscellaneous plantation of seedlings, would, on the average, contain about half of each, and as the date is wind pollinated, and the pollen impalpably fine and light, the fruiting blossoms would mostly receive pollen and an abundance of fruit be set. As an economic proposition, however, in a plantation of choice varieties, such a number of male trees could not be afforded when a few would furnish all the flowers necessary to pollinate the whole grove if the work is done artificially, so in practice, one male tree is set for every fifty or one hundred fruiting trees. The seedling males differ greatly in the time of flowering, and in the amount of pollen afforded, two flowering for the first time at Mecca this spring, proving entirely sterile, the anthers being merely empty sacks. Other male trees flower so late as to be of no value, for their use upon belated fruiting flowers would only produce clusters of dates too late for ripening.

So it comes about that a male variety affording an abundance of potent pollen at a desirable season is highly valued, and offshoots from it are set instead of taking chances on seedling varieties.

With both male and female sorts, the seasonable application of water has much to do with the earliness of flowering, and a tree has recently come under my notice where irrigation had been neglected earlier in the season that upon receiving an abundance of water later, is just now flowering considerably out of time for the variety.

One important difficulty with the work at Tempe, Mecca and the private enterprises at Heber in the Imperial Valley, is the lack of a sufficient number of early male flowers. Flowering begins in February, and while in theory, last year's pollen should be used in such cases, the practical keeping of it in potent condition seems to have failed in a measure with all of these cultivators.

The tying of a little sprig from a male flower into the whisk-broom-like head of a female flower, as it bursts the sheath, looks like a simple process and is, but on the intelligent doing of this at just the right time and in just the right way depends the entire date crop, and in districts on about the border line of date growing territory, late frosts, cold rains or sweeping winds may considerably interfere with success.

Where failure has resulted, the flowers may drop off early, leaving the nearly naked strings of the spike to tell the story, but in other cases they may hold on and the fruit grow, three dates to the flower instead of but one, sometimes reaching a large size and a beautiful appearance, but lacking the seed and power to ripen.. I have seen more than a hundred pounds of fruit of this character upon a single tree. In twelve or fourteen days after pollination has been accomplished, one of the three ovulos of the flower will start into vigorous growth while the other two will fall behind, later on sometimes appearing as scales at the base of their successful rival. I have but once seen two perfect seeded dates ripened from the same flower.

Pollination successfully accomplished, the growers troubles are not yet over. With young trees whose fruiting stalks are produced near the ground the weight of the rapidly developing fruit, a bunch sometimes weighing from 30 to 40 pounds, soon bends them over, and they must be propped up. As a precaution against birds, squirrels, rats and sometimes the neighbor's boys, not to say the neighbor himself, the bunches are sometimes enclosed in stout screen wire bags, but some predatory "animal" occasionally cuts the stalk and carries away bunch and bag, perhaps the only bunch of that variety yet fruited. It is seldom that the entire crop is menaced, as occurred at Tempe, in the fall of 1906, when hordes of migratory rats invaded the plantation, and it was only by great efforts and after the killing of hundreds of them that a portion of the crop was saved.

Scale Pests.

The presence of a dangerous and destructive scale, the Parlatoria blanchardi, on most of the offshoots imported from the north of Africa necessitates thorough fumigation on their arrival in this country. In spite of all precautions this scale has been introduced both at Tempe and Mecca, probably in the deep crevices beneath the leaf bases, and while thorough cyanide fumigations have kept it well in check, it seems likely that the gasoline flame treatment devised by Prof. Forbes will be necessary for its complete extermination. Fortunately, it spreads but slowly and seems to have no other host.

Another genus of scale, the Phoenicoccus Marlatti, commonly known as the Marlatt scale, has been present upon date trees at both Phoenix and Heber, but as it was confined to the bases of the leaves, seemed to do little damage. Recently, however, Mr. Chumard, at Heber, has found it in such numbers upon the bases of fruit stalks of his Deglet Noor trees as to seriously interfere with the full development of the fruit.

Labor.

The labor of the date orchard is pretty well distributed throughout the seasons. There is no portion of it dependent upon a heavy force of outside labor brought on for a particular period, though the gathering and packing will be the most busy time and the hopeful cultivator will be glad to have employment for considerable extra labor at that period, but his wares are not so perishable as to depend on the work of a day, as with strawberries or cantaloupes. In the distribution of the year's work, date growing will compare well with the labor problem in the apple orchard or grape vineyard.

Adverse Seasons.

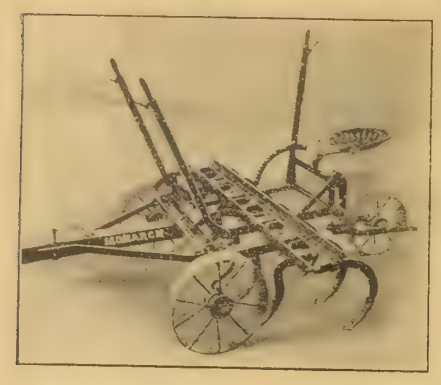
No crop grown is more liable to destruction by untimely rains than the date crop, but the arid character of desert countries is so well established, that these occurrences are rare. During last October the rainfall at the Tempe garden was 2½ inches, a quite unprecedented record. Added to this the rise of the ground water from excessive irrigation of the surrounding fields, and a period of cool nights with heavy dews, and little was lacking to insure the destruction of the crop. Many that ripened, soured instead of curing out, and others started to decay while hard upon the trees. Flies and wasps swarmed in to remind one of the plagues of Egypt. The same conditions with less rain began at Mecca, but before long a drying desert wind set in and the damage was stayed, though an autumn temperature below the normal prevented the ripening of considerable fruit that would have matured in ordinary seasons.

There seems no doubt that the increased humidity due to the proximity of the Salton Sea, only a half mile distant, had a retarding action on the ripening of the fruit.

In the Tempe garden, fruits were ripened in commercial quantities two years ago, though the rats destroyed a considerable part of the crop. Those sold, chiefly of the varieties of Rhars, Tedalla and Birket El Haggi, brought 25 to 40 cents per pound, put up in neat one-pound cartons.

The choice and late Deglet Noor has not yet been successfully ripened at Tempe. Fair specimens of this were secured at Mecca last year in spite of the October rain, and I recently tasted very good Deglet Noor dates from the private plantation at Heber in the Imperial Valley. Several of the new varieties from the M'Zab region of Algeria gave very finely flavored dates in small samples last year. The present season promises to show fruits of many more varieties, and among them several bunches have been pollinated of the rare Menakhor variety secured by Mr. Thos. H. Kearney from Tunis, and of which there are but three or four specimens living in the United States. This superb variety, Mr. Kearney states, is seldom placed on the market, even in Tunis, "being reserved for the tables of the wealthy natives and for gifts to their friends."

OUR MONARCH CULTIVATOR



Is designed for heavy work. Has great clearance (17 in.) between front and rear standards, which permits the working of trashy or lumpy ground, and lightens draught. While designed more especially for field use, it is now becoming a favorite among orchardists where deep cultivation is desired. By the arrangement of levers it can be carried level or deeper on one side if desired. Write

BACTERIA IN ITS RELATION TO SOIL CULTURE.

IN a course of horticultural discussions under the auspices of the Riverside Y. M. C. A. one evening was given to the subject of bacteria. At this meeting Mr. E. L. Koethen gave an address from which we quote:

"Until within quite recent years agricultural experts and scientists believed that the problem of chemistry in the soil was purely a chemical one, which could be reduced to simple terms of action, and reaction of one chemical upon the others.

Most everyone of you present were so taught in our schools, but there were many obscure problems which chemistry failed to explain. The use of the miscroscope has, however, revealed wonders upon wonders, and we now know that without the flora of the soil—so minute, that hundreds of thousands of the germs may exist in a single bit of soil as large as a pea—we can have no true soil fertility.

The processes of decay of organic matter in the soil are brought about through the agency of innumerable miscroscopic organisms called bacteria, and to some extent, fungoids.

In these days we are familiar with the term bacteria and involuntarily associate it with typhus and tuberculosis, diseases of man, and not without reason, for it is now demonstrated that all contagious diseases, and many that have not heretofore been classed as such, have their origin in microbe life. In fact, by far the majority of species are beneficial to human life, directly or indirectly. They are nature's scavengers par excellence. They have economic value on the farm, in the kitchen, in the laboratory, in the dairy, and creamery.

These infinitesimally small microscopic plants, for they are not "bugs" nor animals, are so vast in number that miracles are accomplished by them.

Their rapidity of bacterial multiplication is almost beyond belief. Twenty minutes to a half an hour suffices under ideal conditions for an individual of some of the rod shaped forms to elongate, and to be divided into two, which in a similar lapse of time becomes four.

The conversion of organic matter to available plant food is quite complex, involving not one set of bacteria but a series of them, each in turn performing its peculiar office, the conversion of unavailable nitrogen being the most important. This element as found in the air, or as in blood, and other organic matter, can not be assimilated by the higher plants. It must first be converted into a 'nitrate,' which is a combination of nitrogen with oxygen and some alkali base as lime or soda.

Some bacteria thrive best in the presence of air, other species best when it is excluded. The air lovers in general tend to make plant food available. The air shunners tend to decompose organic matter, and reduce it to the gaseous form, and thus cause the losses of nitrogen; hence drainage and tillage are important. Both forms may do good service in agriculture, and the latter may cause great losses. For instance, when the air is excluded from the soil for long periods by being kept too wet, there may be a loss of nitrogen through the action of air-shunning bacteria.

Sunlight is usually death to all bacteria. Thus, on our light soils too much stirring may cause the death of large numbers of desirable germs.

As to temperatures, the highest efficiency attained is between 70 degrees and 105 deg. Fahrenheit. This only occurs in hot sands where plant life is practically excluded.

A well balanced moisture supply is essential for the largest development of the desirable soil bacteria.

Land that has been scraped for grading is most likely to be deficient in soil bacteria, and such spots invariably show a deficient tree growth. The remedy is to replace a portion at least of the surface soil and apply an abundance of humus making material, especially barnyard manure, as it is particularly rich in nitrifying germs.

Nitrification proceeds best in a feebly alkali soil. If acid or strongly alkali, the process ceases. As the nitric acid needs a base upon which to act, it is necessary to have lime or other alkali present in the soil. Phosphoric acid and potash are also essential for the best development of the bacteria.

By far the largest number of nitrifiers are found in the first foot in soil, in proportion as air is admitted to the lower strata, and as these are warmed the opportunities for deeper location of nitrifiers is enhanced, hence adequate drainage and tillage tend to promote nitrification.

Litman says: "Humus is decaying organic matter in the soil. It is the seat of all important bacteriological activities for the very reason that it furnishes food and energy to the micro-organisms.' He does not specify at what stage the decaying matter becomes humus, nor do we need to care, for the very first effects of decaying organic matter are important to the agriculturist.

While it is important that nitrogen should be available for plant food, it is equally important that the other elements should be found in the soil in a condition which would be available to the higher plants. Especially is this true of potash and phosphoric acid. They are naturally so locked up as to prevent loss of soil fertility by being carried off in surface waters and through leaching in the soil. Hence again the soil flora plays an important part.

In bringing about the decay of gross organic matter, the bacteria liberate a quantity of carbon dioxide gas, which being a mild acid unites with portions of the inert phosphorous and potash compound, making them available. Our soils being rich in unavailable potash, this is important, and accounts for the fact that many growers have obtained excellent results from the cover crops, without the application of commercial potash in orchards that were previously benefited by its application.

If we are to take the soil analysis for a guide, we must conclude that there is an abundance of this element in our soils in this locality, enough to last us for many years, providing it can be made available. The remedy then is not to buy potash, but to add organic matter in such quantities that

it will not only furnish the nitrification needed, but also the carbon dioxide necessary to dissolve the potash.

Litman quotes a case where the analysis showed 30,000 to 40,000 pounds of potash to be present in the first foot of soil to the acre, and yet it was benefited by the application of 100 to 200 pounds of muriate of potash. Yet the abundant addition of humus material to the soil made the application of potash unnecessary. Frequent stirring also helps the process of converting available mineral matter into the available forms.

The above is also true of phosphate. There is no necessity of applying dangerous acid phosphates to our soils if we can make phosphates available by the addition of organic matter.

This is not all. In the composition of the humus making material, and in the humus itself, in the final product are found mild vegetable acids which all act upon the unavailable plant food, and here again the bacteria have furnished the process by which the acids are liberated. Bone phosphates placed on the cover crops just before plowing come in contact with the decay acid more readily, and are hence subject to more rapid decomposition.

In conclusion, we would say that the question is often asked when our application of fertilizers becomes available. Litman makes these statements: 'From practical experience and from vegetative experiments, it is known that green crops and animal manure usually benefit the crop most in the first year after their application. Also the nitrogen of ammonia salts and liquid manure, or of such compound of dry blood, nitrifies very rapidly.'

In the general discussions which follow this paper the Riverside Press reports as follows:

General Discussion.

Fred Reed led the discussion and the lecturer was asked many questions regarding his views of certain phases of soil biology and fertility touched on in his paper.

As to the time to apply phosphates, James Mills thought the best season was just before the cover crops were put in, as the cover crop would make phosphates available in the spring of the year, when needed by the tree. If he were using bone, he would put it in during July, August or September for the cover crop, bringing it a step nearer the tree; when the crop was turned under it would then become available for the orchard. In his opinion fall was the best time to use phosphates and potash. Mr. Koethen stated that if he thought his place was deficient in phosphoric acid, he would apply it now and not wait until fall.

J. H. Norton, superintendent of the citrus experiment station, was asked many questions concerning the composition of soils and the best condition of moisture for bacterial growth, and by means of the blackboard illustrated the chemistry of denitrification in a very interesting manner.

Owing to the large percentage of lime in the soil of this valley, it seemed to be the consensus of opinion that if any lime were applied cover crops should be used in connection and barnyard manure in abundance. Soils here are poor in humus and hence the grower must be guarded in the use of lime.

It was the opinion of some present that the disking in of cover crops was not advisable, as the portion of the crop that was left to dry on the surface was lost by oxidation and a large percentage of nitrogen was returned to the air.

In a Chicago Exchange we note: "The West prefers navels and the minute these come into market, western dealers drop Florida's. It costs nearly as much to haul Florida oranges to Chicago as to bring California fruit here, and this item is becoming much more expensive for Florida as the producing section moves further south in that state to escape the frost."

The orange growers of southern Texas have formed an organization with about 300 growers as members. Among the first things taken up was a plan for the extermination of the white fly in the state. To accomplish this they will endeavor to have the legislature pass laws ordering the complete destruction of all trees and shrubs which harbor the white fly in the citrus fruit territory of the state.—Florida Produce News.

All About the Orange and Lemon

Is told in our new book on Citrus Culture, embracing every phase of the subject from the seedling plant to the final disposition of the fruit in the Eastern market. The largest and best book on the subject ever printed—60,000 words, 100 illustrations. You will want a copy, which we will send you for the small sum of 25 cents. Remember we are the largest growers of orange and lemon trees in the world.

Deciduous Fruit Culture

By J. W. Mills

CROWN GALL OF THE APPLE.

CROWN gall is a term applied to certain warty outgrowths or excrescences upon the apple, pear, peach, raspberry, etc., forming chiefly on the parts below ground. On the apple these growths are more apt to occur on grafted trees at the union of the root and the cion, but they may form at any place where the roots have been injured in transplanting, etc.

Recently, Dr. Erwin F. Smith and his associates in the Bureau of Plant Industry, U. S. Department of Agriculture, have demonstrated quite conclusively that crown gall is caused by a specific bacterial parasite. Moreover they have shown that it is very omnivorous in its tastes, being able to cause warty outgrowths or galls on a surprising number of different and unrelated species of plants when these plants are inoculated with pure cultures of the organism. Galls have been produced in this way upon the following named plants: Peaches, almonds, apples, hops, Paris daisy, walnut, grape, radish, tomato, raspberry, etc.

Not long ago the Maine Experiment Station purchased 60 apple trees from a leading New York nurseryman. The package in which they were shipped bore a tag stating that the orchard from which they came had been officially inspected and found free from disease. Three out of the 60 trees or 5 per cent of the shipment had well developed crown galls upon them. This experience indicates that every orchardist should very carefully inspect all stock. All trees showing evidence of crown gall should be either returned to the shipper or burned, and future orders placed with nurserymen who can and will furnish trees free from disease. Under no condition should trees be planted which show growths of this kind upon the roots, for not only will it result in an unthrifty and unprofitable tree, but it will also infect the soil with the crown gall organism and endanger other plants.—Chas. D. Woods, Director, Maine Ex. Sta.

WALNUT ASSOCIATION.

Regarding the recently formed Walnut Growers' Association and its aims. The Anaheim Gazette gives the following:

The association will incorporate under the law recently passed by the legislature relating to non-profit sharing corporations. This allows any persons or incorporated associations to appoint a selling agent to manage their marketing and is not in conflict with any anti-trust law.

The new association which will likely be known as the "California Walnut Growers' Association," will be composed of one director from each local association and an additional director for each 50 cars which the several associations may have shipped in 1908.

The stock of the associations, which will be without value, will be held by the directors, one share each. The objects of the new association are for co-operative and more economical marketing and carrying on of the business of the various persons or associations for which it will be agent, and to assist in obtaining a true and reasonable value for the walnuts produced by them.

The new association is to have full and complete power to sell all walnuts of the various associations, either through brokers or agents, as may seem advisable, though no change is contemplated in the present method of selling and receiving the money for the walnuts as they are loaded on the cars, but all differences that may arise between the local associations and the brokers will be adjusted by the new association as it will be the party making the contract with the broker. The new association will have its own inspectors and will establish the grade for marketable walnuts which will prevent each broker making a distinct grade for each association, and sometimes for each car.

There will be no cutting of established price as no one but the central association will be allowed to name a price or sell any walnuts. All payments will be made to the central association and the money at once sent to the association from which the walnuts were shipped. There will be no inducement for any association to cut price in order to sell its walnuts, for in case any walnuts should remain unsold at the end of the season they will be carried by all the associations alike, and the orders will be distributed pro rata according to the amount of walnuts each association may have.

A penalty attaches to any association violating its agreement and a provision is made for withdrawing from the new association.

A meeting will be held soon at which it is expected every association, including those just formed, will join the new association, which will then be ready to begin the work of making contracts for handling the crop this year.

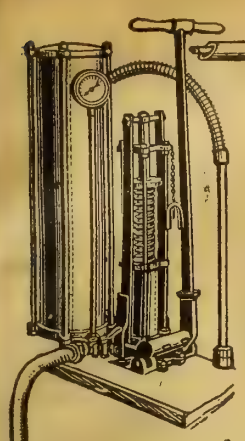
This is the greatest step in advance that the walnut growers have ever taken, as it assures the buyer of a fair margin of profit; assures the broker that no one will name a lower price and demoralize the market; assures the grower that his walnuts will be marketed at the least cost and without danger of prices being beaten down by irresponsible persons, and that he will get a fair share of the price paid by the consumer. It also assures the grower that there will be no over-production, as the new association can advertise and in other ways bring walnuts to the notice of people who are not now buying, and make his groves more valuable.

MORE APPLES NEEDED.

Radical changes are necessary in the culture of apples on this continent or the United States and Canada will be forced in a few years to import apples instead of exporting them. If it had not been for the enormous crops in the orchards of the Pacific and northwestern states and provinces this year an apple famine would have resulted.

Many of the middle western and eastern states reported small yields this season, due to failures in numerous instances, but generally because of pests. Orchards have been neglected and in scores of places the trees have been permitted to die because of the lack of even ordinary attention.

In 1896 the total product of the crop



See That Patent spring ?

It means much to the fruit grower who realizes the need for effective spraying, but deplores the ordinary pump with its exhausting labor, its unsatisfactory spray and its continual clogging and bother. This spring is found only in

Bean Magic Spray Pumps

It would be found in others, but the Bean Patents prevent it. This spring divides the work, permitting the operator to do half the work at each stroke of the handle. And he works against but half the pressure indicated on the gauge. It saves just one-third the labor. Two sizes of Bean Magic pumps; both have Bean patent spring, non-clogging ball valves, and other exclusive features.

Our illustrated catalog No. 21 describes ten sizes of hand pumps, and contains much valuable spray information, and formulas. Catalog No. 22 describes Power Sprayers. Both books sent free. Write for our special offer; state number of acres and kind of fruit.

of the country was 69,070,000 barrels, or 177,675,000 bushels. Since then hundreds of thousands of acres have been added and yet the government reports show that the aggregate crop in all the states in the Union was not more than 25,000,000 barrels or 62,500,000 bushels in 1908.

There will always be markets for apples. There can never be an overproduction of first class stock. It is in fact impossible at the present time to produce the quantity of good apples requisite to meet the demand. This is evidenced by the fact that England, Germany, France, Denmark, Australia and the Orient are already drawing on the orchards in Washington, Idaho, Oregon and British Columbia.—"Horticulture."

SPRAYING FOR THE CODLING MOTH.

The kind of fruit you grow gives you your reputation. A reputation for good, clean fruit is worth as much as the fruit itself. Maintain such a reputation for yourself and your locality by destroying the codling moth, says Washington Experiment Station.

Spray your trees with arsenate of lead, using one pound to fifty gallons of water. Begin to spray when 80 per cent. of the blossoms have fallen, and have enough outfits on hand to be through in eight days. Use bordeaux nozzles, because they throw a coarse, penetrating spray, and do not use more nozzles than the capacity of your pump will supply and still keep the pressure up. Set the nozzles at an angle of about 45 degrees, either by bending the end of the rod, or by means of an elbow coupling. Throw the spray directly into the throat of each flower. To do this the nozzle will have to be held above the branches most of the time, and the spray rained down. A mist spray or simply throwing a coarse spray into the tree will not fill the lower calyx cup, and that is the only part of the tree that needs the spray. If your trees are taller than you can reach with the rod, build a tower platform from which to spray. Get above the branches and spray down.

To reach the bottom of the calyx cup, much pressure is absolutely necessary. Do not spray at less than 80 pounds, and if possible use 150 to 200 pounds. Stay with a tree until the bottom of every blossom is filled, even though it may seem a great waste of time and material. Select a blossom here and there and cut it in two, to see if your spraying has filled the cup beneath the stamens. If it has not, your spraying is not thorough, and you should spray again immediately. Watch that you do not miss the ends of the branches.

Most worms enter the apple through the bottom of the calyx cup. When this is poisoned there can be no late worms, for the early worms are the parents of the later ones. Just how carefully or how carelessly you do the first spraying will determine the number of wormy apples you you will harvest. Later sprayings are unsatisfactory. They are hard to time correctly, and they save little fruit.—Green's Fruitgrower.

A "cute" little booklet, "a story with a moral," with a few quotations from President Taft, has been received from the Western Electric Co., 463 West St., N. Y. It is worth the postal card required to write for one.

For Mehring Foot-Power Milking Machines see O. J. Weber Co., 225-227-229-231 East Sixth St., Los Angeles, Cal.

ARSENATE OF LEAD.

The leading insecticide for summer use.

3 pounds arsenate of lead.

50 gallons water, or bordeaux mixture.

Arsenate of lead is in the form of a thick white paste, which dissolves readily in water. It adheres to the foliage for a long time and does not "burn" the leaves. For codling moth also for canker worm, tent caterpillar, and all insects which eat the leaves.

When pruning fruit trees, keep the low head in mind. Trees of this kind suffer less from sun-scald, and the fruit is easier to gather. It is claimed that the fruit will color better, and surely low-heads will stand hard winds better than tall trees.

Why go to the expense of setting out an orchard and then neglect it? That looks like land, time and money wasted. An orchard worth setting out is worth caring for right.

In fertilizing the orchard, remember that the feeding roots extend far out from the trees.

BIG MEN BEHIND A BIG IDEA.

Of course the Kalamazoo Stove Company of Kalamazoo, Michigan, is not the only satisfactory stove company in the country, but it would be hard to find a better—a more progressive—a stove company which has its business more thoroughly in hand—or is more keenly alive to the interests of the user of stoves. The selling plan of the Kalamazoo Stove Company—from-factory-to-user—is world famous and their slogan, "A Kalamazoo Direct to You" has become a household word. Their theory being that you can always buy at less cost from the manufacturer than through the dealer, a theory which their prices prove beyond question. When in addition to the advantage of this low cost price, the freight is prepaid also by the factory—as is done in their case—the combination seems an ideal one for the purchaser.

Their enviable success as makers of stoves that give satisfaction is due in large measure to their Vice-President and General Manager, William Thompson, seconded by the hearty co-operation of the other members of the company. All of Mr. Thompson's time, thought and tireless energy are devoted to the perfecting of stove manufacture. The planning and designing, the buying of raw materials, the manufacturing and finishing processes, the selling plans, great advertising campaigns and even the correspondence are carried on under his personal supervision.

Mr. Thompson is a man of striking personality—of strong convictions—an originator always—never a copier. A man with broad human interests, without foible or pretense—just a plain man of the people, keen in intellect, but with the kindliest heart in the world. A man whom every one of his customers would like to meet and do business with personally if that were possible.

One of the Kalamazoo Stove Company's characteristics is a cheerful confidence in the integrity of human nature. They believe that—other things being equal—a man will generally keep his word—do what he promises to do. During the past few years letters have come to the company's office from time to time asking if Kalamazoo stoves were sold on credit. Heretofore they have been obliged to return the same negative reply to all these inquiries; to their regret and the disappointment of the inquirer.

Beginning with this season the Kalamazoo Stove Company announce that they are ready to handle these inquiries for credit more satisfactorily. From now on charge accounts will be opened on their books with all responsible persons who want to buy a Kalamazoo. The convenience to thousands of this new feature of the Kalamazoo selling plan is instantly recognizable and will tend toward a mammoth increase in the sale of Kalamazoo stoves and ranges.

The company has been working for some time to bring about this change of policy in their business and they seem justified in being optimistic as to results, both for the firm and their customers.

In a recent conversation Mr. Thompson said: "If people have confidence enough in us to take our word for the quality of our stoves then we will have confidence enough to take their word that they will pay for them." And generous terms are therefore made wherever a customer asks for credit.

Catalogs and full explanations of terms—cash or credit—will be sent free upon request to the Kalamazoo Stove Company, Kalamazoo, Mich.

Small Fruits and Vegetables

THIS MONTH.

NEARLY everything in the vegetable garden may be planted this month which has not been planted earlier. Of, course, the usual planting of radishes, lettuce and other green truck which is wanted coming all the time will be made. The spading which should have been done heretofore has put the soil in condition for the finest of seed. Small seeds should be planted very lightly and covered with fine rakings from the corral. Even in frostier sections it should be perfectly safe to plant all the early potatoes. Of course, melons and sweet corn are in order, and those who have been anxious to get the earlier melons have probably had seed planted in cold frames for some time. In very cold sections and where the ground is very cool, melons may possibly be frosted yet. In that case they may be planted in paper boxes to be later transferred to the garden row. Everything should be crowded as fast as possible to get out of the way of the army worms, or cutworms which may come in a month or so later. In fact it is a wise preventive to plant at the edge of the garden so that a deep furrow may be laid around it to prevent the army worms from marching in on the garden. If such a furrow is laid in very dry soil, it will crumble to a certain extent after drying, and with the perpendicular side toward the garden is a very good preventive from the attacks of this pest. The manner of mixing poisons for these worms will be given in this department later.

POTATO DISEASES.

IN a leaflet issued by the Arizona Experiment Station the diseases affecting potatoes were enumerated and remedies given as follows:

Potato Scab.

Potatoes are grown to a considerable extent in Arizona and are subject to several diseases. The "scab" is found only on the tubers, which become roughened and shrunken and cracked in the diseased areas. The fungus is spread almost entirely by means of diseased tubers used for seed.

Remedy.

It can be entirely prevented by soaking the tubers to be used for planting in a solution of formalin, one-half pint to 15 gallons of water, for two hours. Then cut and plant as usual.

Early Blight.

This disease is very destructive in practically every country in which potatoes are grown. It destroys the leaves and sometimes the stems but not the tubers. It appears at first as brownish dead spots over the leaves, especially near the margins. The leaves finally become quite brown, curl up, and become dry and brittle, and the plants have the appearance of premature death.

Remedy.

Spraying with Bordeaux mixture is a successful preventive. Plants already attacked cannot be saved but the disease will be held in check by spraying. Where the disease is prevalent spray first when the plants are six or eight inches high and repeat every two weeks during the entire growth of the plants. Where the disease appear for the first time spray the whole field at once, and repeat at intervals of two weeks.

Rosette, Black-leg, or Little Potatoes.

This variously named disease does serious injury to potatoes in Arizona. In some states it is the chief disease of potato crop failure. It attacks the tubers, and also girdles the stem just at or beneath the surface of the ground causing a conspicuous blackening of this region. There is at first an abnormally vigorous development of tops and the formation of small tubers above ground at the base of the plant or even in the axils of the leaves. Then the whole plant weakens and dies prematurely.

Remedy.

As the disease is mainly below ground spraying is useless. The trouble usually starts with diseased seed, so the remedy is to use only healthy tubers for seed. If the seed is from fields where the disease exists it should be treated with formalin as for scab. All old diseased parts must be carefully collected and burned. Occasionally a soil becomes impregnated with the fungus and then there is nothing to do but cease growing potatoes on it for a time.

Dry Rot of Tubers.

This wide-spread potato trouble is very prevalent in Arizona, and frequently causes a loss of a large proportion of stored potatoes. While causing some injury to the growing plant the chief loss is the rotting of the tubers after they are harvested. At first the tubers appear quite sound, no external indication of the disease being present. If, however, the tuber is cut across at the stem end there are seen distinct black areas in the shape of streaks through the flesh or in the form of a ring. This blackening of the tissues slowly spreads until finally the whole of the interior of the tuber is affected. The first external indication is a shrinking and drying up of the stem end. This continues until the entire tuber is a shrivelled hardened mass.

Remedy.

As the fungus is confined to the underground parts spraying the plants is of no service nor can the tubers be treated as the fungus is internal. The disease is first introduced into a soil by means of diseased tubers so that the most important precaution is to avoid the introduction of the trouble by using only seed free from the disease. If the seed tubers are not perfectly sound they should be cut at the stem end and examined for the black areas. Diseased tubers if thrown out will infect the soil, so they should be burned, and on no account thrown on manure piles, or fed to stock. Unless the soil is badly infected clean seed will give healthy tubers, but diseased seed invariably results in diseased tubers.

Remember that the farm machinery manufacturer made the following statement: "If the farmer cared for his machinery as he should, there would be a need for us to manufacture but one machine where we are now putting out two."

The Ornamental Garden

THIS MONTH.

THE ground is warming so that practically all ornamentals may be planted. The queen of fall months, the Crysanthemum, should be put in during the month. Carnations will do their best planted at this time. Summer flowering bulbs, like the gladiolus should be planted soon, though some of the bulbs may be saved until the later planting, where one wishes continuous bloom from these bulbs. Most of the annuals may be planted, as zenias, balsam, snapdragon, and in fact all others, so as to be at their best during the hot months, as may cannas, elephant ear, dahlias, coleus, montbrettia, tuberoses and salvia.

In trees, it is rather late for any deciduous ornamentals, but evergreens like the orange, lemon, lime, and loquat should be gotten in the ground as soon as possible. The ground is now warming up and these trees will take root quickly and be ready for the warm summer months.

Give the lawn a good heavy dressing of either thoroughly rotted manure or best commercial fertilizer, which has a large percentage of phosphoric acid. The best way to have a good lawn is to give it plenty of fertilizer for the grass roots. It is also an excellent month for starting a new lawn.

MAKING A GARDEN.

A woman's experience given in Country Life in America has an inspiration in it. It applies more particularly to Eastern conditions, but nuggets which will pass current in California may be picked up from it.

"The fences were of rough, unpainted boards. Thirty yards away was a white-brown building containing a woodshed and quarters for the horse; but no horse was there. The only living spots upon the landscape were a rooster and half a dozen dejected hens. It was not even a place for selfrespecting chickens to live in, for the yard was paved with stone."

"Don't you know that there is not enough earth in this place to make a mud pie?" asked the skeptical Man of the House.

"I will make earth," said the wife.

It was nearly winter, when one day a neat load of sod arrived, followed by another and another. The sod lay in a heap, untouched, and when the cold weather set in the servant used the sod pile as a sink, upon which all the refuse from the house, except ashes, was thrown.

Everybody for blocks around soon knew that a flour barrel in good condition was worth ten cents at this back door, and by the end of March thirty barrels were stowed in the tenantless stable.

A hotbed was contructed in early April, the storm windows from the house being used for sash, and after the earth had heated the seeds were planted and the garden begun. The hotbed soon contained a tiny jungle of growing plants, and with the aid of an "odd job" man the foundation of the garden was commenced. The fence was buttressed with great boxes, 24 inches deep and 36 inches across, arranged like two facing L's, the narrow space between the upper extremities. The thirty barrels were converted into sixty half barrels and arranged about the yard. Meanwhile, a pile of sand, another of "black muck," or mold, and a third of granite boulders were dumped in the yard.

Neihboring ash heaps were levied upon and the barrels and boxes filled within twelve inches of their tops. Then with a spade and garden fork the sod heap was attacked.

The grass roots were quite decayed and powdered easily. The man sifted it through his fork and threw the lumps away, and then mixed sand and decayed sod, using equal parts of each, with which the boxes and barrels were filled. Then the granite rocks were erected in the center of the yard into something resembling an Egyptian pyramid, and the interstices filled with the prepared soil.

Man is Convinced.

By this time the emulation of the man of the house was aroused, and he employed a carpenter to build a flower-bed twelve feet long by four in width and eighteen inches deep. It was constructed of two-inch plank and stood upon stout, short legs, the bottom being water lined, while at the sides stood a barrel upon a scaffold, arranged so that the bottom was three inches above the surface of the bed. Tiling was laid in the bottom of the bed and covered with small stones and broken crockery. Then the bed was filled with earth.

Trailing Vines.

Toward the first of May the work was completed, and then from hanging pots which ornamented every window were cut slips of the trailing vines called Creeping Charlie, Wandering Jew and Kenilworth ivy. Each slip consisted of a stalk about two inches long with two leaves at the top and two at the bottom, and they were set about four inches apart along the edges of the boxes and barrels, with the lower leaves under ground.

Here and there along the inner edge of the boxes were planted scarlet runners, with threads arranged for them to run on.

The last of May the boxes and barrels were filled with young plants from the hotbed, and from the sunny windows in the basement were added quantities of Madeira vine that had been growing there in house boxes and which were set to climb where no scarlet runners had been planted. The following week the house plants and hanging pots were brought out and placed in advantageous places, and then the desert began to bloom.

The man of the house filled his barrels twice a week with a mixture of guano and water, and after allowing it to become "ripe" turned a tap and allowed the water to run down into the tiling, from which it soaked up into the earth, and after the earth was thoroughly soaked, another tap connected with the tiling was turned, and the water run out into a great tub.

This was practical irrigation and the superflous water was used for manuring the plants in the boxes and barrels.

Rioting Color.

The result was a luxuriance of color and foliage such as no one in the vicinity had ever seen. Balsams of the variety that grow to twelve or eighteen inches were four feet high, stocks were over two inches in diameter and other flowers were propor-

What a Few of Our Advertisers Say

Read what our advertisers say as to the value of the CULTIVATOR as an advertising medium:

Fresno, Cal., Feb. 4, 1909.

Cultivator Publishing Company,
733 Merchants Exchange Bldg.,
San Francisco, California.

Gentlemen:—Replying to your favor of the 3rd with reference to your paper as an advertising medium, beg to say that we find same one of the best papers in the horticultural field for this purpose. We have given you an advertisement for several seasons, in fact ever since we have been in business, and results obtained have been very satisfactory.

In placing our Fall advertising the Cultivator is the first paper on our list. Our system of keying our ads has demonstrated that your paper furnishes us with a very large patronage during the season, and we are pleased in every way with the paper you publish.

Yours truly,
(Signed) THE FRESNO NURSERIES.
C. A. Chambers, Secretary and Manager.

San Francisco, Cal., Feb. 4, 1909.

California Cultivator,
733 Merchants Exchange Bldg.,
San Francisco, California.

Gentlemen:—My client, the Paraffine Paint Company, has used space in the California Cultivator for a good many years; in fact ever since I investigated your circulation in 1902 and found your statement to be correct and your circulation well distributed through the prosperous farming sections of California.

Mr. E. G. Judah, the Los Angeles representative for the Paraffine Paint Company, has repeatedly informed me that the results from your publication have been very satisfactory.

Yours very truly,
(Signed) EDGAR M. SWASEY.

Petaluma, Cal., Feb. 4, 1909.

California Cultivator,
733 Merchants Exchange Bldg.,
San Francisco, California.

Gentlemen:—It gives us pleasure to say that we have been advertiseing in the California Cultivator since we started in business and have found it to be, without doubt, the best medium for reaching the class of people whom we desire, of all papers on the Coast. Our continued use of the Cultivator indicates our idea of its value as an advertising medium.

Yours very truly,
(Signed) COULSON POULTRY & STOCK FOOD CO.,
Sherman C. Leonard, Secretary.

California Cultivator, Los Angeles, Cal., Feb. 24, 1909.
Los Angeles, California.

Gentlemen:—Replying to yours of February 12th, we wish to say that we are very much pleased with the results we have obtained from advertising in the Cultivator. We get a great many inquiries, and in a large number of cases they prove to be live ones, to whom we eventually make sales.

It is our intention to continue our advertising with you.

Yours very truly,
(Signed) WESTERN GAS ENGINE COMPANY,
Per W. H. Thompson, Secretary.

Santa Cruz. Cal,, Feb. 4, 1909.

California Cultivator,
733 Merchants Exchange Bldg.,
San Francisco, California.

Gentlemen:—I am delighted with my advertisement in the Cultivator. The inquiries give me no rest, and postage on the replies costs more than the advertisement itself.

Yours truly,
(Signed) HENRY SHAW.

California Cultivator, Fresno, Cal., Feb. 4, 1909.
733 Merchants Exchange Bldg.,
San Francisco, California.

Gentlemen:—Enclosed please find check to cover amount of our account to date.

We have advertised in a good many mediums this season, and find that the greatest number of answers and inquiries come from the readers of the California Cultivator.

Yours very truly,
(Signed) S. W. MARSHALL & SON.

California Cultivator Company, Santa Ana, Cal., Feb. 17, 1909.
Los Angeles, California.

Gentlemen:—I am pleased to say that my advertising in the Cultivator brings good results. In most letters I receive from outside, I find "saw your ad. in the Cultivator" and I try to do the rest.

Thanking you for your generous treatment, I remain,

Yours truly,
(Signed) GEO. B. WARNER,

California Cultivator, Dixon, Cal., Feb. 22, 1909.
Los Angeles, California.

Gents:—Enclosed find $1.35 for advertisement one month. Am well pleased with result of my first advertisement. It pays to advertise in the Cultivator.

Yours respectfully,
(Signed) J. R. SNEAD.

California Cultivator, Pasadena, Cal., Feb. 16, 1909.
Los Angeles, California.

Gentlemen:—Permit me to say my advertising with the Cultivator has paid me better in proportion to amount invested, than any other medium I ever used. This may be due to either of many causes—it is important at this time to say my advertisement is now being carried by over 100 papers in the U. S.

Yours respectfully,
(Signed) J. B. WAGNER.

Portland, Oregon, Feb. 24, 1909.

Cultivator Publishing Company,
115½ No. Broadway,
Los Angeles, California.

Gentlemen:—We take pleasure in stating that we have advertised with you continuously for over five years and have felt perfectly satisfied with the results. We are constantly receiving letters from all over the Pacific Coast in which reference is made to our advertisement in the "Cultivator."

We consider the Cultivator one of the best of weekly papers on the Pacific Coast for advertising purposes.

Wishing you continued success and increase in your circulation, and with kindest regards, we are,

Yours very truly,
(Signed) NATIONAL WOOD PIPE CO.,
By Walter Carnes, Secretary.

Los Angeles, Cal., Feb. 13, 1909.

The Cultivator Publishing Company,
115½ No. Broadway,
City.

Gentlemen:—Acknowledging your letter of February 12th, asking us as to results received from advertising in the California Cultivator, wish to say that we are more than satisfied.

We have now been using the Cultivator steadily for about two years and we have received more returns and more inquiries than from all other papers combined. We believe that you are publishing a first class up-to-date paper and the inquiries received by us show that your circulation is distributed through this Southwestern country.

Truly yours,
(Signed) ARNOTT & COMPANY, INC.
Willard Arnott, President.

San Fernando, Cal., Feb. 16, 1909.

Cultivator Publishing Company,
115½ No. Broadway,

Gentlemen:—As this is our first year's business, and doing quite a little advertising in other papers and we find the great amount of inquiries and buyers come through the Cultivator, as they take a delight in mentioning, "I saw your advertisement in the Cultivator," and I want to thank the Advertising Manager for he said it would bring better results than any other paper in Southern California, and it has been very satisfactory to us,

I am, yours very truly,
(Signed) SAN FERNANDO NURSERY COMPANY,
By W. J. Mann, Secretary and Manager.

Ontario, Cal., Feb. 20, 1909.

California Cultivator,
Los Angeles, California.

Gentlemen:—We have been too busy lately to even change our ad. The rush of mail order business has been simply immense. We have been using advertising space in your valuable paper each planting season for several years and, therefore, must give the Cultivator due credit for helping us build up our business to what it is today, which is now SECOND TO NONE in Southern California.

Wishing you continued success we are yours very truly,
(Signed) ARMSTRONG NURSERIES,
By J. S. A.

Anaheim, Cal., Feb. 10, 1909.

The California Cultivator,
Los Angeles, California.

Gentlemen:—Enclosed please find check of $2.00 for enclosed bill. I think this will cover all my bill. Please discontinue my advertisement as I have sold all my stock. That little advertisement has done good for me, and am well pleased with the investment, and anyone who is interested in farming and the progress of it, ought not to be without the California Cultivator.

Yours very truly,
(Signed) ADOLPH RIMPAU.

Sunnyvale, Cal., Feb. 5, 1909.

The California Cultivator,
733 Merchants Exchange Bldg.,
San Francisco, California.

Gentlemen:—We wish to state that we find the California Cultivator one of the best mediums that we use. We have obtained splendid results from your paper.

Wishing you all the success and prosperity of the season, we are,

Yours truly,
(Signed) JUBILEE INCUBATOR COMPANY,
Per A. W. Bessey

Santa Cruz, Cal., Feb. 6, 1909.

California Cultivator,
733 Merchants Exchange Bldg.,
San Francisco, California.

Gentlemen:—I find that the California Cultivator pays me better than any other paper on trees and berry plants. 1,216 letters in December and January.

Yours truly,
(Signed) A. MITTING.

Covina, Cal., Feb. 19, 1909.

California Cultivator,
Los Angeles, California.

Gentlemen:—We are very much pleased with the returns received from advertising in the Cultivator. Scarcely a mail arrives that does not bring us inquiries referring to our advertisement in the Cultivator. We do business with a fair percentage of all who write us.

Yours very truly,
(Signed) THE KELLAR THOMASON MFG. CO.,
Per Elmer Thomason.

Live Stock and Dairy

Dairymen and stockmen are requested to write of their experience. Mrs. Sherman is always willing to answer queries and this, with experience of other workers, will make this department of greater value.

By Mrs. Minna E. Sherman

SILAGE FOR PIGS.

AFTER the way spoken of last week of rotating the land to crops that the pigs harvest for themselves, a few further questions have come in to be answered. The crops of alfalfa are sown once in six years and each pig lot is sown in turn, one new one each year. This, of course, means that land that is moderately moist or can be irrigated is used. There are often high spots that are too dry for any of these crops which are made productive when sown to rye. The pigs harvested it and it sows itself for several years without our doing more to it than giving it a good harrowing each fall.

Alfalfa Hay.

Alfalfa hay when cut for the pigs must have the leaves on it. The mower should start to go when the first simmer of bloom shows, if not a few days sooner. I like to have to pick the buds open on the blossoms when the mower begins to sing its song of pleasure as it wantonly cuts off the alfalfa head. This alfalfa hay should be raked at once and cured in the cock and then hauled in at once when it is dry, not let stand in the cocks to blanch out. This the pigs will eat up clean, every straw of it. There is no need to grind or chop it for them. Suppose, however, the alfalfa hay is not perfect, but mixed with foxtail and weeds. We put the young pigs in the same lot with heifers from six months old to eighteen and they eat this kind of hay up clean. Foxtail hay should be fed from the ground and it does not often then get into the eyes of the cattle. If enough is put out in the afternoon each day from the barns to leave the worse on the ground until the next morning, the dews will dampen the foxtail and make it soft enough to be eaten readily. The seeds of foxtail are full of nutriment and when the cruel barbs are softened the stock rather relish the flavor.

Silo.

There is a place for everything, and everything should have its place. The silo is the place for the first cutting of alfalfa every time. The foxtail makes alfalfa silage of great value for horses and cattle and pigs, and it gives good results in feeding to all three classes of stock. In making silage of alfalfa it is necessary to cut it into three or four inch lengths to encourage the packing and it must be made wet, very wet, to make it pack closely and heat up quickly. The fact is, as nearly as I can find out, every time the silo fails to make good all that is claimed for it, in California, that the amount of water is insufficient. We have a dry climate in the summer time. Though this winter makes one wonder if it will ever stop raining, still June will soon be here and it will be dry and warm again. The crops are not water filled and the absence of dews renders them still more dry. We forget this when we make silage. The first alfalfa silage I ever made came out black and dry. I knew, then, it needed water to make it moister, and ever since we crowd on the water, putting a full head of water running on the alfalfa as it passes into the elevator, so that a constant drip of water falls under the elevator all the time. I have never gotten it too wet yet. This silage comes out tender and a faded green and it sweet smelling; the stock eat it up clean. The pigs are very fond of it and eat alfalfa silage more readily than they do the corn silage.

Filling the Silo.

In Fresno you have, no doubt, heard it is sometimes a trifle warm in summer. Well, this warm time is when we are making silage and we do not know if that is the reason or not, but the silage will get too hot here if we fill a large silo straight full at once. When ten feet is in the silo the men that are filling are put on other work until the mass has heated up to as hot as it can and the temperature begins to fall again; when it reaches at a foot from the top, 120 degrees, we fill in another ten feet and stop again. This will make a good silage out of corn or anything we put in. While it is not so absolutely necessary with corn, it is necessary to observe this rule closely with alfalfa and oats and peas. Bean straw, too, will overheat readily.

Alfalfa Meals.

These have proven disappointing to the pig feeders as they are costly, and the results are not as good as when we feed the alfalfa as hay or as silage. Sometime ago, I was asked why a farmer could not make alfalfa meal. The only reason I know is that it seems to be quite a process of drying the hay almost to dessication, then grinding it and sacking it up. The dryer the alfalfa is the better for this purpose and of course the loss of leaves in handling has been greater and more stems are ground than a regular proportion of alfalfa hay. This results in a higher per cent of fibre in the meal and a reduction in the digestible availability of the food elements. In California, except for chicken feeding it is not worth while to make alfalfa hay into meal. The old cow and the old pig are the best mills and the cheapest. You may remember the old man that boiled all the foods his pigs ate, when asked why? He said to save the pigs time in eating. His questioner, then asked him, "What was a pigs time worth any way?" So say we. What better use can Mr. Pig put his day's work to, than in chewing up afalfa hay.

Alfalfa.

We have been sowing some of the new alfalfa as Dr. Shaw has kindly sent us seed. The men are greatly interested in this work and those that are getting ready to go to the mountain to cut lumber, are asking the others to be sure to remember how these new plants grow. The first of the barley planting is in head and the machine is cutting it to give the cows a nip as the meadows are still too wet to pasture. The bermuda pasture affords the cows scant picking. The winter has given too much rain,

DE LAVAL SEPARATORS Make The Best Butter

The one purpose of every thinking buyer of a cream separator is the making of the most and the best cream possible, whether for home buttermaking, creamery patronage or any other use to which cream is put.

It is possible to "claim" almost everything for the various makes of cream separators, but the one indisputable fact that would-be competitors do not even attempt to get around is the unquestionable superiority of the DE LAVAL machines in the making of the best butter.

Year after year, dating back to the invention of the "ALPHA-DISC" system of DE LAVAL bowl construction, butter made by users of DE LAVAL machines has scored highest and won all higher awards in every large and thoroughly representative butter contest throughout the world.

Beginning with the first great annual contest of the NATIONAL BUTTERMAKERS ASSOCIATION IN 1892 and ending with the 1908 contest, not only the HIGHEST but every anywhere near high award has been made to users of DE LAVAL separators and more than nine-tenths of all exhibits scoring above 90% in quality have been DE LAVAL made.

The Roll of Honor All De Laval Users

The First Prize winners and their scores at every convention of the National Buttermakers Association since its organization in 1892 have been as follows:

1892 Madison, Wis., Louis Brahe, Washington, Iowa...Score 98.
1893 Dubuque, Iowa, C. W. Smith, Colvin's Park, Ill...Score 97.
1895 Rockford, Ill., F. C. Oltrogge, Tripoli, Iowa.....Score 98.
1896 Cedar Rapids, Iowa, Thos. Milton, St. Paul, Minn. Score 97.82
1897 Owatonna, Minn., H. N. Miller, Randall, Iowa....Score 98.5
1898 Topeka, Kan, Sam'l Haugdahl, New Sweden, Minn. Score 98.
1899 Sioux Falls, S. Dak., A. W. McCall, Creston, Iowai Score 97.
1900 Lincoln, Neb., H. T. Sondergaard, Litchfield, Minn. Score 98.
1901 St. Paul, Minn., E. O. Quenvold, Owatonna, Minn. Score 97.
1902 E. L. Duxbury, Green Bay, Wis.....Score 98.5

1908 J. C. Post, Hector, Minn.....Score 98.
(There were no conventions in 1894, 1903 and 1905.)

In the great 1908 contest 504 of the best buttermakers in the United States competed, with first, second and third, and all important awards, being made to users of DE LAVAL machines.

At each of the big Chicago National Dairy Shows DE LAVAL butter has made a CLEAN SWEEP of all highest prizes, and at the December, 1908 Show, when instead of butter there was a cream contest, under the supervision of the Dairy Division of the United States Department of Agriculture at Washington, first and second prizes in both classes were won by DE LAVAL cream.

Going back further, DE LAVAL made butter received the GRAND PRIZE at the ST. LOUIS WORLD'S FAIR and as well at the last PARIS WORLD'S EXPOSITION.

In all the hundreds of important state and country contests the world over for twenty years the superiority of the DE LAVAL separator in the making of fine butter has been conclusively proven.

THE EXPLANATION IS TO BE FOUND IN THE IDEAL DESIGN AND CONSTRUCTION OF THE DE LAVAL SEPARATING BOWLS AND THE THOROUGHLY PRACTICAL CONDITIONS UNDER WHICH DE LAVAL MACHINES MAY BE OPERATED AND USED.

A new 1909 DE LAVAL catalogue—affording an education in this as in other features of separator knowledge—is to be had for the asking.

UNITED STATES

U.S. Cream Separators

Best To Buy

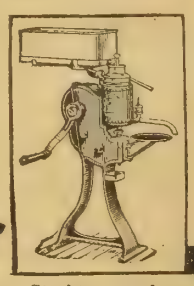
Everybody knows the name **United States** on a Separator is an **absolute guarantee of Superior Quality, Long Service and Absolute Satisfaction.**

That is the best sort of economy; it means a saving of money to you. Why then run any risks with "cheap" makes?

See the U. S. Separator Dealer

Let him show you how a **United States Separator** is made, its perfect mechanical construction, strong, solid, one-piece frame, no bolts to shake loose with wear. Scientific construction of the Separator bowl. You can readily see for yourself how the purchase of a **United States Separator** means economy for you. If you do not know a United States dealer let us send you his name.

A request by postal card for United States Separator Catalogue No 20 and mentioning this paper, will bring you a beautiful hanger lithographed in colors.



VERMONT FARM MACHINE CO.
Bellows Falls, Vt.

Prompt Delivery Assured California Customers from Stockton warehouse. No delays. Address all letters to Bellows Falls, Vt.

The Empire for Simplicity

When you buy a cream separator you certainly want a simple machine. You cannot afford to buy one that is complicated and full of gear wheels, shafts, and extra bearings. The simpler any machine, if it does its work, the better it is.

The Empire has one wheel, which drives the worm wheel shaft, and that drives the bowl; nothing to give you trouble or get out of repair. When you are ready to turn, the Empire is ready to run.

Send for catalogue or see a machine and you will be convinced.

Empire Cream Separator Co. Ltd.
No. 85 North Sixth Street, Portland, Oregon

Malthoid Roofing

Saved the lumber, coal and building plant of A. I. Schowalter & Co., of Halstead, Kan., from fire last March. The south wind blew the flames from a barn filled with hay directly on the sheds of this company. These sheds were roofed with Malthoid, while the sides were covered with corrugated iron. The heat was so intense that it ignited the wood back of the corrugated iron and it was only with difficulty extinguished. The fire-resisting qualities of Malthoid Roofing saved the roof, which was subjected to the most heat.

Malthoid Roofing is fire-resisting and durable.

so that the mares and colts as well as the young stock and pigs have all shared the silage with the cows, until it has all been fed out and the cows are wearying for a good stomach full of green stuff. Fortunately there is plenty of sweet hay for them, yet and they have it spread out daily before them on the bermuda where all can share alike in it. While the tame things on the ranch are delightful, yet the old mother coyote that lives in the swale with her two funny half grown cubs is very interesting. She shows great intelligence, yet some day she too will go down before the gun and the gunner will be proud. Every year a new one comes down to take her place. These coyotes make long runs after the jack rabbits, and seem by their tactics of running wide nearly, always to be successful in catching him. Some day I will have to write to you of the wild things of the ranch from the larks and "kill deers" up to the coons, badgers, skunks and coyotes. The place is full of these shy ones, that peep out to see if any one is near before they go to their pleasures or follow up their work of making a living.—M. E. Sherman.

GRUBBY CATTLE.

From January to June most cattle, especially those which are kept largely on the open range, suffer from grubs under the skin. These grubs are the large maggots of the ox bot fly, which is a common pest in Europe and America.

The injury is not large in each individual case, usually, but taking the sum total throughout the country is estimated by the United States Department of Agriculture at $30,000,000 each year. The loss is to be attributed to several sources. In beef animals, the hides which bear holes made by the grubs are discounted at the tanneries at about a dollar each. The places where the grubs are lodged between the hide and the meat are shot with blood and pus and must be trimmed away. In dairy cattle, the annoyance and pain caused by the grubs and flies entail a loss of from ten to twenty per cent in the productivity of the animals.

The life history of the insect must be understood in order to treat the trouble intelligently. In the spring and early summer, the flies appear. These are about half an inch long and appear somewhat like a honey bee. The body is black and covered with yellowish-white hairs on the fore part and reddish-brown on the hind part. The flies lay their eggs on the heels, legs and flanks of the cattle. The cattle are terrified by the presence of the flies and are frequently stampeded by them. It is a curious fact that the flies will not go over water to reach the cattle. Often the latter spend a large part of the warm hours of the day standing in water or on small islands or rocks in runing streams to avoid the flies.

After the eggs are laid, they find their way into the mouths of the cattle when these lick the hairs to which the eggs are attached. The saliva of the cattle appears to release the little grubs, which attach themselves to the walls of the throat. Here they bore through the walls and slowly make their way through the flesh of the animal, until in about six months or more they find themselves under the hide. They then make a small hole through the hide through which

they are able to breathe more freely and, consequently, their growth from this time forward is much more rapid.

When the grub has reached its full size, it makes its way out through the opening, drops to the ground, and goes through the resting stage before it appears as the adult fly.

Bearing these facts in mind we can readily see that the pest may be attacked at two places in its life history. If we can prevent the laying of eggs or kill the grubs, we can reduce the injuries.

The grubs under the skin may be killed in several ways. One common method is to rub down the lumps on the hide with a round stick, such as a broom handle, thus killing the grubs where they lie. Oil or lard may be applied to the holes in the hide, which will stop the breathing pores of the grub and kill it. If a little carbolic acid is put in the lard, it will help the wound to heal more quickly. By pinching on either side of the lumps, the grubs will often be forced out. They should be killed by the foot if they drop to the ground. The holes may then be treated with carbolized lard. This method is to be preferred, for it does not leave the grub under the hide to fester.

Dairy cattle and those kept in close range may be largely protected from the egg laying by spraying or smearing vile smelling oil or grease on their legs and flanks. Train oil and fish oil are often used for this purpose. Any vile smelling stuff will answer, for the benefit lies in keeping the flies away from the animals. The applications should be kept up during the spring and early summer.—S. Arthur Johnson, Colorado Agricultural College.

STOPPAGE AT THE POINT OF TEAT.

A very common trouble in the ordinary dairy is to find an animal with the point of the teat closed, either due to a bruise of the teat itself or to infection of the milk duct which causes a little scab to form over the point of the teat and unless this is properly handled with care and cleanliness, the infection is apt to cause a loss of the entire quarter.

The proper manner in which to handle and treat such cases is to thoroughly wash the teat in an antiseptic solution, then dip a teat plug into a healing ointment and insert it into the point of the teat, allowing same to remain from one milking to another. In this manner closure of the point of the teats can be overcome in a very simple and satisfactory way.

Never use a milking tube if it can be possibly avoided as there is much danger of infecting the entire quarter by the use of the tube.—Dr. David Roberts, Wisconsin State Veterinarian.

Cows will fall off in milk if water is not within easy reach. When in full flow of milk they require, it is claimed, 50 per cent more water than when dry.

Where hogs are bred for pork, it is wise to breed two litters a year. In breeding sows for their progeny to keep up and increase the herd, breed once a year.

No openings in your cow stables to admit sunlight. This is a great mistake. Sunlight is death to many forms of germ life.

AMERICAN FENCE

To get the most out of a farm, every square foot must be either tilled or else made to produce feed for live stock. A fence all around the farm, then cross fences, making more and smaller fields—permitting rotation of crops and change of pasture—are first essentials in making possible maximum earnings.

Here are two great fences—the best square mesh and the best diamond mesh. We selected these two styles years ago, after careful study and advice from many of the most experienced and successful farmers, the correctness of which has been verified by actual results in the field. These fences are the simplest in construction; are made of any size or weight of wire desired and perfectly adapted to all uses and conditions.

If you want square mesh, buy American; if you like diamond, buy Ellwood. You can safely take the verdict of the millions of farmers who have tested and tried out these two great fences. Dealers everywhere, carrying styles adapted to every purpose. See them. Catalogue for the asking.

ARABIAN ALFALFA.

When in the Imperial Valley recently we saw at Holtville, samples of growth made by Arabian alfalfa. Also Professor Shaw's division of the demonstration train exhibited growth of this alfalfa alongside of the common or Chilian alfalfa, showing more than twice the growth in new introduction. It has been but a short time since the Government has imported the seed of this new alfalfa and has distributed it to a few growers. We believe it was first planted at the Pomona Experiment Station in 1903, though not attracting attention until the last year or two. The largest piece of which we know is one at Holtville, which belongs to Washington Wilson. This piece is seven and one-half acres and the seed was supplied to Mr. Wilson on condition that a like amount be grown by him and returned to the Department. As yet this planting has not demonstrated any disposition to bloom, but after one or two more cuttings this spring Mr. Wilson intends to let it stand in the hopes of securing a good crop of seed.

Another planter at Thermal has one acre, only planted this last fall. It is growing well with a promise of a good cutting soon. One characteristic of this new plant in addition to being a rank grower, is that while its stems are somewhat larger than the ordinary alfalfa, they are hollow and do not contain so much fibre as does the common alfalfa. Cows eat it more closely and show by the milk flow the wonderful producing power the plant has. Mrs. Wilson of Holtville, remarked particularly on this quality, saying that their cow when changed from the Arabian hay to that of the common Chilian, the cow showed a remarkable shrinkage in quantity; also demonstrated plainly that the hay was not as much to her liking as the Arabian.

If this promise of greater worth and bigger crops is made good after more extensive experience, the wise dairymen will make effort to secure a seeding of this valuable plant. It is unfortunate, however, that the seed is not to be had in any quantity at this time, it is probable that another fall will show a great increase in this seed, as every farmer who has a quantity of it planted should be willing to seed his plants and extend the acreage of this valuable plant.

LAND FAKES.

The frequency with which Easterners coming into California are swindled out of their good money by some so-called real estate agent or "locator" of fine Government land, calls attention to the fact that more publicity should be given to this style of swindling. That might seem a hard term to use in some cases, but it is no more than it deserves. Sub-divisions have been made in Antelope valley and town lots sold in a desert section which have no values whatever; other lands of fertility, but where absolutely no water can be secured for it, has been used as a bait for buyers by the agent who would "for a consideration," put the tourist next. This land which may be of value in itself is so located as to be of absolutely no value to the homeseeker. We note in the Imperial Standard along the same line the following warning:

"For a year or more there has been but very little land open to original filing which has any tangible prospect for getting water. Despite this fact, unscrupulous persons have recently "located" homeseekers on tens of thousands of acres of land for which there is no assurance of water, charging a fee for their services. There is an abundance of good land in the valley having water present or in early prospect, to be had for reasonable prices, but the person who pays another for "locating" him on government land in this valley must understand that the prospect is that he will lose his money and fritter away his time. In particular, the homeseeker is warned against several land sharks in Los Angeles who make a specialty of 'locating' claimants."

The fee for this "locating" ranges from $10 up, and of itself is not so serious, but loss of time and of railroad fare is often illy borne by the unfortunate.

ARBOR DAY.

We have received from Edward Hyatt, state superintendent of public instruction, a copy of Arbor Day Manual which contains full information of the meaning of arbor day to the young people of California. It is filled with illustrations and is well worth being in the hands of everyone who is interested in this custom of planting a tree. There are many pages of sentiment similar to the following: "What earnest worker with hand and brain, for the benefit of his fellow men, could desire a more pleasing recognition of his usefulness than the monument of a tree, ever growing, ever blooming and ever bearing wholesome fruit?"—Irving.

THE NEXT TRIP.

No dates have been given as yet as to when the next demonstration train will make its tour, but probably it will be not far from the middle of April. The road to be covered will lie largely in Los Angeles, Orange and Ventura Counties; the first stop will probably be Los Angeles, with Norwalk, Downey, Whittier, Buena Park, Anaheim, Santa Ana, Westminster, Smeltzer, Los Alamitos, Compton, Long Beach, Burbank, San Fernando, Santa Paula, Santicoy, Mantalvo, Oxnard, Moorpark, Ventura, Carpenteria, Santa Barbara, Goleta, Guadalupe, San Luis Obispo and other towns to be touched on a two weeks' trip.

A WINNER.

It is not often that the Cultivator calls attention to its merits as a newspaper or advertising medium, but we can not refrain from noticing the testimonials of pleased advertisers who have given the paper a fair trial during the past year. The list could be indefinitely enlarged if space permitted. On another page will be found a few of the many letters received in nearly every mail from subscribers, and mainly from the northern part of the state.

The growth of the paper during the past few years has been marvelous. When the present manager first purchased an interest in the paper it was struggling along in "red ink," with about nine thousand circulation, an inadequate advertising rate and was practically an unknown factor in the state. During the past two years its circulation has largely increased, its advertising rates doubled and the business of the paper more than doubled in every line. It is one of the very few publications in the country and probably the only one in the state that did more actual cash business in 1908 (panic year) than in 1907.

It is the largest farm paper on the Coast, and the dollar a year price makes it the popular weekly of the state. While it is the largest and cheapest paper in the state, its editorial contributors are the best and highest priced to be obtained. It is constantly seeking original articles from the very best writers along the different lines of cultural development for California and Coast conditions.

During the coming year other valuable features are to be added and more and more expended to keep the paper in the front rank. Suggestions for its betterment will be welcomed from any source and we ask for the paper a friendly recognition of the efforts made for its advancement.

KEEP OUT THE PESTS.

The action of Horticultural Commissioner Jeffrey, in quarantining a carload of cotton seed shipped into the Imperial Valley from Texas, is commendable, and in fact one of the steps necessary. If California is to protect herself against the introduction of innumerable other pests, and if cotton growing is to be made a business of any importance in Imperial Valley and Arizona, every effort should be made to keep out the weevil which has been so destructive in nearly all the southern states. The car received in question was put in charge of County Horticultural Commissioner, W. E. Wilsey of El Centro, and the shipment was given a very thorough fumigation with hydrocyanic acid gas.

It is essential that those living in the Imperial Valley should join with the commissioner in this effort to keep out the pest, and to that end the only safe course is to be sure that the county commissioner is informed of every shipment which is made, in this way, with thorough fumigation before the seed is released from quarantine they should be successful. We are not informed as to whether the Arizona farmers are as vigilant. They should be.

PUT THEM ON FARMS.

Holland has a plan by which able-bodied paupers are made to earn an honest living. There is a tract of public land, containing 5000 acres, which is divided into six model farms, and to one of these is sent the poor person applying for public relief. If he voluntarily serves till he learns agriculture he is allowed to rent a small farm for himself and be what is called a free farmer. Every pauper who is thus reclaimed to honest regular industry is so much gain to the state. There is also a forced labor colony, where beggars and vagrants are sent and made to do farm and other work whether they like it or not.

We see no reason why California may not work out a similar plan and teach criminals and paupers the blessing of honest and independent labor. Too much of our treatment of criminals and paupers leads to more criminality and pauperism. Let us teach agriculture, or some trade, and common honesty to the paupers.

There was a belief common for many years that boys, like wheat, must be well thrashed to get the best out of them. The rod is no longer plied in the school or family, and yet there is after all a pretty fair crop of boys.

Agricultural Notes of the Pacific Coast

Northern California

The Gridley creamery will install an ice plant.

Brown's Valley, Yuba county, will soon have a creamery established.

Employees of the Gridley cannery will hold their annual picnic June 4.

Armour & Co. have entered the Petaluma field for the purchase of eggs.

Biggs is discussing extensive improvements on the levees of the Feather river.

Vineyard pruning and also plowing is the order of the day at Windsor, Sonoma county.

It is rumored that the Selby Smelting Company will erect another smelter near Benicia.

Anderson, Shasta county, is preparing for a rose festival to be held about May first.

Goat shearing on ranches near Colusa has been begun. One goat owner is shearing 1700 goats.

District No. 6 in Sutter County proposes to improve the levee system so there will be less danger of an overflow.

Humboldt county dairymen say that green feed is now exceptionally fine, though it was late in starting growth this spring.

Shasta county papers complain that the Sacramento Valley Development Association does not give their section a fair show.

Thrips appeared in the orchards of Suisun valley soon after the first of March and it is feared they will do vast damage this season.

Owners of large tracts of land near Rescue are pasturing goats on brush lands which they wish cleared and finding good results from the experiment.

The Dairy Exchange of San Francisco has a rule that all butter squares must be full weight or at least within two per cent of the specified weight.

Dried fruit in many sections of the Sacramento valley has been all picked up and there are very few parcels of any size now remaining in growers' hands.

The large icing and pre-cooling plant under construction at Rosedale is nearly completed. It will cost about $750,000. It is 900 feet long by 120 feet wide.

Notwithstanding the recent heavy rains and soaked conditions a forest fire near Mill valley caused many residents to get out and fight to save their homes from the flames.

The Board of Supervisors of Alameda county has appointed as a Horticultural Commission Messers. E. O. Webb of Hayward, W. A. Tyson of Niles, and Fred Suelberger of Oakland.

The Sonoma County Co-operative Poultry Association is having a fight to maintain its existence in face of attacks by organized interests which make offers better than this association has offered producers for eggs. The producers should stand pat, for the better offers will be short lived, once the association goes to pieces. Colusa county is discussing the advisability of voting bonds for good roads.

Central California

Thrips are affecting the prunes of the Santa Clara Valley.

Reedley, Fresno county, reports extensive orange planting.

Great preparations are being made for "Raisin Day"—April 30th.

The Farmer's Union continues to increase all over the raisin producing section.

There will be quite extensive planting of orange trees in Tulare county this year.

Recently planted alfalfa near Turlock has been somewhat injured by drying winds.

Ceres desires a new cannery and hopes it will be established within the near future.

Raisins are selling somewhat better than in the past but still at ruinously low prices.

One Kerman peach grower claims a profit of more than $300 per acre on last year's peach crop.

Experiments are being made at Kerman, Fresno county, in the planting of Turkish tobacco.

Turlock has organized a large Local of the Farmers Union, with over a hundred charter members.

San Joaquin county has just voted nearly $2,000,000 for the construction of 288 miles of Macadam road.

A Visalia cow which had dieted on baling wire dropped dead because of a piece of wire penetrating the heart.

The Farmer's Union is planning for a big outing on Raisin Day, April 30th, to celebrate the day and eat raisins.

Notwithstanding the hard fight made by the New York importers on the tariff on figs, a duty of 2½ cents is contemplated in the proposed bill.

Recent meeting of fruit growers at San Jose called to form some agreement as to the disposal of dried fruit, adjourned without definite plans being formed.

The probable retaining of the 2 cents a pound tariff on Zante currants gives assurance to raisin producers. Raisins are unchanged and are to be left at 2½ cents.

A bounty of $20 per scalp is allowed for mountain lions and ranchers along the west side of San Joaquin valley are anxious that this bounty be claimed.

Raisin growers at Hanford have suggested the plan of disposing of raisins in a popular ten cent carton which would with proper advertising, the promoters hope, aid in disposing of a great many raisins.

April 30 has been fixed upon as "Raisin Day" and it is hoped the entire United States will join in celebrating the day and eating raisins. The Southern Pacific Company has promised that every dining car upon that great system will that day serve raisins.

The State Board of Health is making an experimental trip with a special car furnished by the Southern Pacific Railroad Company, in which among other exhibits are models of sanitary farm buildings. These models are made for the purpose of giving better ideas to the farmers so that milk of a higher grade may be produced.

Southern California

Coachella valley will raise turkeys to a greater extent than heretofore.

Corona has discovered a fine deposit of gypsum and will ship large quantities of it.

Imperial Valley recently forwarded 22 cars of cattle, sheep and hogs in one week.

Imperial Valley estimates above a million sacks of grain to be harvested this spring.

With cabbages hovering near the $40, the cabbage growers are feeling very happy.

Seven hundred ostriches have been transferred to the new ostrich farm at San Jacinto.

Extensive planting of orange trees is being made at Shermuttville, Orange county.

County Bee Inspector Pleasants of Orange county reports indications of a good honey crop this year.

A San Marcos, San Diego county rancher, is levelling ground for a large planting of eucalyptus trees.

The Imperial valley has a Japanese melon growers association, incorporated with a capital stock of $5,000.

Ranchers on the peat lands above Huntington Beach report double the planting there was last year of sugar beets.

It is reported that the Yuma Experiment Station, maintained by the Government, will be transferred to the Imperial valley.

Prof. Ralph E. Smith of the Pathological Institute addressed the orange growers of Highland recently on gum disease.

An Eastern syndicate has bought land west of Bloomington, San Bernardino county, and will plant orange trees this spring.

The Imperial valley cantaloupe crop is practically all planted and it is now estimated that nearly 6,000 acres have been planted.

The water is turned out of the ditches of the Covina Irrigation Company and repairs and cleaning of ditches are in progress.

Nine valuable horses were killed in the Antelope valley by drinking of water strongly impregnated with alkali, standing in surface pools.

The car of cotton seed received at El Centro last week was well fumigated and is distributed to the planters. It contained eighteen tons of seed.

Cuttings of spineless cactus supplied by the Plant Introduction Garden at Chico are being planted in the Pala Indian Reservation, San Diego county.

The Imperial Valley Dairymen's Association is raising the standard of dairying in that country and has determined that milk offered at the creameries shall be received according to its quality.

The Fullerton and Whittier sections have decided that the purple scale which has spread largely over that section, is the worst pest which the orange grower has to contend with. One grower alone paid for fumigating his orchard $3000 during the last year.

The Coast

Alfalfa seed is commanding $18.50 per hundred at Spokane.

The Government will make a big display at the Seattle Exposition.

Western Oregon peach trees have been seriously injured by late frosts.

The Roosevelt Dam in Arizona is now 120 feet above the old river bed.

The Horticultural Society at Eugene, Oregon, holds monthly meetings.

Pendleton, Oregon, reports wool prices running about 5 cents in advance of last year.

The Washington County Dairy Men's Association met at Forest Grove, Oregon, last week.

The sheep men of Eastern Oregon are offering a heavy bonus to hunters who are after the coyote scalps.

An effort is now being made by a Wyoming rancher to control the coyote by distributing contagious disease.

The peaches and apricots on Snake River, Washington, have been seriously injured by cold weather in January and February.

Finley, Washington, has opened up as a wool shipping point, owing to the river transportation company making it a stopping place.

Alaska is making an effort to secure an appropriation from the National Congress for $1,000,000 in aid of a good roads campaign.

The Farmer's Union is having a wonderful growth in Western Oregon. At one meeting recently held at Pendleton the attendance was so great the hall would not hold it.

The Puget Sound Warehouse Company has begun to make a charge for handling grain at 50 cents per ton, a reduction of 25 cents on each ton.

Farmers at Colfax, Washington, have organized a Co-operative Farmers Union and are building an immense warehouse for handling next fall's crops.

A bill has been introduced into the Ariozna Assembly, calling for the purchasing of the territorial fair grounds and authorizing the payment of $30,000 therefor.

A tract of land of over a half million acres has been set aside in Western Oregon, in the Olympic National Forest, to be given over for breeding grounds of elks.

A farmer at Montesano, Washington, claims that from six high grade Jersey cows he sold milk so as to net during the year an average of $142.95 each.

Members of the Farmer's Union in Colorado have refused to raise beets for the American Beet Sugar Company in Colorado. The farmers demanded a flat rate of $5.00 per ton or no beets.

Some wool contracting has been reported in Eastern Oregon, but the producers are slow to sign up at present prices which are ranging from 16 to 18 cents. Montana is reported to be paying 20 cents.

The first dairy association to be formed in Clark county, Washington, is the Lewis River Dairy Association; the object will be to raise the standard of stock and secure better returns to the dairymen.

Don't Forget Quality

MIDLAND Poultry Food

Is based on ***quality*** and it is quality in Poultry Food that produces eggs. ***Cheap filler*** and ***cheap grain*** will ***not*** make eggs. ***Midland Poultry Food*** contains only the ***choicest*** cereals and animal food the market affords. When the chicks are hatched don't feed them anything for 24 hours, then feed them the best dry Chick Feed you can get. We say that is

West Coast Chick Feed

Read what others say:

SAMUEL R. KELLAM, former president of the L. A. Co. Poultry Association, says: "West Coast Chick Feed is the best feed for young chicks I have ever used. I have given this feed a thorough test, and have always found that it produced fine, large, healthy chicks."

MRS. A. BASLEY, the celebrated poultry authority, says. "I want some more of your West Coast Chick Feed, for it is excellent. It is purer, cleaner and appears better balanced than other feed I had been using, and to tell the truth, I have been experimenting, feeding both together, and they always eat yours in preference."

Ask your neighbors, for there is more of "West Coast" sold in Southern California than all other kinds put together. If not sold by your dealer send us $3.50 and we will send a 100 lb. sack, freight prepaid within 300 miles.

Route One ***Santa Barbara, California***

Profit in the Poultry Yard

By Mrs. Frank Metcalf

We solicit short articles of a practical nature from the fancier and utility breeder, giving their experience with poultry. All inquiries pertaining to feed, management, disease and its prevention will be answered through these columns.

CHICKEN CHAT.

ONE of our valuable contributors wishes practical talks on the profits to be made in raising poultry.

Now, I am going to copy a record from an old note-book of how I made a profit one year a long time ago, back east, and compare prices of feed with prices of feed here, and see wherein the difference lies.

Twenty-seven dozen eggs were set in April, under hens, with eggs at 12½ cents a dozen; 203 hatched, of which 160 were raised. A sudden storm took 27 at one time. Those storms which come apparently out of a clear sky in Ohio, after which one may wander around searching under dock leaves and other big weeds for missing chicks, finding them almost lifeless, stretched out stiff on the ground and only recovering with the best of care, while many are never found.

The rest I lost died young, as chicks will.

I marketed them in September, realizing 50 cents each for them, prices being 15 cents per pound for some and only 12½ for others.

The cost of raising them consisted of $1.00 for 10 shoe boxes for coops being laid upon their sides, and doors made of the fronts fastened on with old pieces of leather for hinges, and buttons. One board was taken out and old pieces of wire netting put on for ventilation, making a vermin (rat) proof coop which accommodated one hen and twenty chicks nicely.

These chicks were raised upon cornmeal, and consumed 28 bushels of corn at 25 cents per bushel, in the ear, we taking it to the mill and having it ground. The eggs cost $3.38. I bought 50 cents worth of oyster shells, making the total outlay for the chicks, $11.88, but they had the run of the whole farm, and picked up half their living around the barns and in the fields.

That is how eastern farmers' wives make their pin money, and they usually have it too. Here the prices of feed would be about twice what it was there, but the chicks can be marketed as broilers at 25 cents a pound at from two months to ten weeks old, so the profit is about the same in the end, if one works equally hard, and does not trust too much to the climate.

The cornmeal would not answer here, and I later learned to use less of it back there in summer, but give these old figures for what they are worth.

Not always did I have as good a record. Many troubles arose from time to time to discourage one. Thieves were one of the things we never could rest easy for, for they visited our roosts at night while we were asleep and robbed us of our whole season's work, often.

Here there seems to be very little thieving, or at least I have never had a moment's worry, nor have I lost any.

The Inglewood Poultry Farm has a market for all its broilers at a price which enables it to pay small producers 25 cents per pound for broilers, and this will be found the best way for a beginner to market his product, until he is in a position to furnish a stated number at regular dates. Sell to the dealer who is under contract whenever possible, which saves the time necessary to hunt up customers, and market singly.

Of course feed is higher in the east now than when this record was kept, and the market reports give the following prices: Saturday, March 20th, prices for feed in Ohio were as follows: Cornmeal, $1.45 per cwt; cracked corn, $1.45; wheat, per bushel, $1,20; barley per bushel, 80 cents; buckwheat, 80 cents shelled corn, 75 cents per bushel; oats, 58; alfalfa meal, per hundred, $1.35 to $1.50; bran or middlings, $1.40 to $1.50 per hundred.

Inglewood prices for same date: Cornmeal, $1.80; cracked corn, $1.90; oats, $2.15; wheat, $2.15; bran, $1.70; shorts, $2.05; wheat bran, $1.50. Barley $1.60 all per hundred pounds.

Eggs in Ohio are quoted 18 cents; eggs in California, 18-22. Chickens quoted in Ohio at 19 to 20 cents per pound, and in California at 23 to 26. So the prices of poultry and eggs keep about enough higher here in California to pay the extra cost of the feed, while the warmth of the climate and the pleasure of working outdoors here as compared with the disadvantages back there, give the chicken business in California a decided advantage over the east. Here one can gain health while working out doors, while there one must be extremely careful or one will lose what health he has. I have chased after chickens in the snow, to come down with a severe and dangerous attack of pleurisy in my old Ohio home more than once, while here the outdoor work for the fowls is a pleasure.—Mrs. Frank Metcalf.

THIRTEEN TENS TO REMEMBER.

Here are a few rules for you, under the decimal system. Though not exactly correct, they are about what should be the case.

Ten hens in a house ten by ten feet are enough.

The yard should be at least ten times as large as the floor of the house.

Ten weeks from shell to the market is the time allotted a chick.

Ten cents per pound is about the average price of hens in market for the whole year.

Ten cents should feed a chick ten weeks, and it should then weigh two pounds if highly fed, the ten cents covering the greatest abundance of food.

Ten months in the year is usually the highest limit of time during which a hen will lay.

Ten hens with one male is about the proportion.

Ten quarts of corn, or its equivalent, should feed a hen ten weeks, if she is of a large breed, but ten quarts in three months is about a fairer proportion.

Ten pounds is a good weight for

males of the larger breeds, one year old.

Ten eggs is the average number to each pound.

Ten flocks each consisting of ten hens, are enough for the acre.

Ten chicks, when just hatched, weigh about one pound.

Ten hens should lay about one thousand eggs during the year. This allows for some laying more than one hundred eggs each, while others may not lay so many.—Poultry Keeper.

A FEW FACTS ABOUT FEEDING.

Flaxseed meal added to their morning ration will help make the plumage bright and glossy and will brighten the color of the comb and the ear lobes.

Leg weakness is not uncommon among the larger varieties of fowls, and it occurs most frequently where the growing chickens are being fattened rapidly for market. The best remedy is plenty of exercise and plenty of bone-forming material, such as crushed bone.

For doing their best work hens require a variety of food. Three or four of the principal grains fed whole or cracked, a mixture of bran, cornmeal and beef scraps fed in hoppers or mixed crumbly with milk or water, and a frequent feed of green stuff such as mangel wurzels and cabbage, furnishes a good variety.

Foods rich in oils should not be fed to laying hens except in small quantities, especially in summer. When they are debilitated from attacks of lice a tablespoonful of linseed meal for every six hens given in a soft mash will often be helpful, since it regulates the bowels. Sunflower seed given two or three times a week will often be found beneficial.

Young chicks have very little storing capacity and need to eat frequently. It is best to feed at regular hours, giving them all they will eat up clean at each feeding, and in such variety as to maintain a good appetite. This is especially desirable when the fowls are intended for market, as it promotes quick growth and early maturity.—Kansas Farmer.

WHITEWASH FOR POULTRY HOUSE.

At the request of many subscribers, we re-print the following recipe for whitewash, which has been tested and found good:

Slake one-half bushel of unslaked lime with boiling water, keeping it covered during the process. Strain it and add a peck of salt dissolved in warm water. Add also three pounds of ground rice put in boiling water and boiled to a thin paste; one-half pound of powdered Spanish whiting and a pound of clear glue dissolved in warm water. Mix all these well together, and let the mixture stand for several days. Keep the wash thus prepared in a kettle or portable furnace, and, when used, put it on as hot as possible, with painters' or whitewash brushes. This whitewash has been found by experience to answer on wood, brick and stone nearly as well as oil paint, and it is much cheaper.—Pacific Homestead.

SEX OF GEESE.

As to distinguishing sex of geese, will say that where they are running naturally on the farm it is not so difficult to distinguish the sex, but when cooped and in a somewhat frightened stage it is quite difficult because you cannot always make them speak. The voice is the only true guide, the gander's voice being sharp and masterful while that of the goose is a coarse droll tone.

The breast bone is no true guide; in fact, if pressed and placed on the block the breasts of both will have the same appearance; that is, the single and the double breast. It is not the bone that gives it that appearance, but is a sort of fleshy lap and is liable to be double on the goose or on the gander, the age sometimes having something to do with this. The same is true of the neck.

I well recall an instance I had to deal with while superintendent of the poultry department of the Wisconsin State Fair. We had judged the geese and the awards were placed and a protest was made that a certain exhibitor who had won first on his White Embdens had shown two ganders, while the awards had been made on pairs. I called the attention of the judge to this and we both tried by every possible means to dis-

$100 Cash Free to You

I sell "SUCCESS" Incubators on trial. I guarantee to refund the money after you use the machine if you do not find them to be exactly as I claim. No other company in this state will do this. Up to this date March 15th, not a single customer has asked for his money BACK either on a "SUCCESS" INCUBATOR or a "SUCCESS" Brooder. I will give you $100 cash if you prove this statement is not true. Is this a good record? Does it not prove that these machines are what we claim them to be? Does it pay you to spend from $5 to $20 more than we ask for an Incubator that will positively give you a good hatch EACH and every time. Some incubators hatch good once in a while, ours hatch EVERY TIME if the eggs are reasonably good. I make

Fireless Brooders

that will raise every healthy chick.

I handle over 240,000 chicks yearly through the Pioneer Hatchery, I know how to BROOD them. Send for FREE catalogues and circulars.

Heavy snow banks on the mountains and in the canyons guarantee a good water supply for next season's irrigation.

Southern California was granted a good soaking rain last week, which gives added assurance of the grain and hay crop.

tinguish their sex. They both had a masculine appearance, but as we could not get them to talk there was nothing left for us to do but to probe after the sexual organs, when we discovered them to be a pair. The judge was a man of long experience, but the two of us were at sea, so the reader will see that it is very difficult even for an expert to always distinguish the sex to a certainty, unless they are on their every-day range, when it is easy just from appearance, the gander always standing straighter and quite erect.—Iowa Homestead.

PRESERVING EGGS IN WATER GLASS.

The Washington Experiment Station sends the following instructions as to water glass preservation of eggs:

"The desirability of some simple, cheap and satisfactory method for preserving eggs is apparent to everyone. A method of this sort which would enable farmers, poultrymen and consumers to put away eggs when they are plentiful and comparatively cheap, and preserve them until the winter season, when they are scarce and high in price, would be of very great value. A large number of methods have been suggested, but only two or three have proved practical or satisfactory for general use. Of these the water-glass method, using 5 and 10 per cent solutions, and lime-water-salt-brine mixture method (1 pound of quicklime, half pound of salt and one gallon of boiled water) were tested by Professor Thatcher. He found that eggs can be kept in good condition for home use for at least eight months by immersing them in a water-glass solution or in lime-water and salt brine, although those preserved in water-glass appeared to come out in better condition than those kept in the lime-and-salt mixture.

Other experimenters have succeeded in keeping eggs to their entire satisfaction in solutions of water-glass as dilute as 5 per cent, but the author's experience was that a stronger solution gave a better preservation. It seems probable that a solution halfway between the two which were used, in strength, would be better than either of these, since it would doubtless give a better product than the weaker solution and would not deposit sediment, thereby gradually losing strength, as the stronger solution did.

The cost of preserving eggs in a water-glass solution of the strength just described, exclusive of the cost of the containers, would be less than 1 cent per dozen. Water glass can be obtained of any wholesale drug firm at a cost of about 10 cents per pound, and a pound of it properly diluted should be sufficient to cover 12 or 15 dozen eggs, the exact amount required depending upon the size and shape of the container.

Any vessel which will hold water and which can be covered tightly enough to prevent evaporation will do as a container for eggs put up in this way. Stone jars are preferable, as they are very easily cleaned and prevent evaporation almost perfectly. Wooden kegs can be used, but in case this is done care must be observed to see that the solution does not become too strong on account of the water absorbed from the solution by the keg.

AUCTION

AT 10 O'CLOCK A. M.

Tuesday, April 6th

On the old Cook Ranch 2½ miles southwest of

BURBANK

On Central Ave. 1½ miles northeast of Toluca. Take S. P. train leaving Arcade depot at 7:50 a.m. to Burbank. Teams in waiting.

65 Dairy cows and heifers; 1 thoroughbred bull.

50 Head Fine Dairy Cows, mostly Holsteins and Durhams, a few choice Jerseys, all young and in good condition, fresh and coming fresh, large milkers, in fact as fine a herd of dairy cows as you can find in Los Angeles County. 15 head Fine Heifers.

1 Thoroughbred Holstein Bull 3 years old.

This herd is out of the dairy district and prospective buyers will do well to attend this sale, as everything will not bring the prices that they do in other localities. Anyone wishing to inspect this herd prior to the sale will be met at Burbank by appointment by the owner and taken to the ranch, where you can see this stock milked and tested. Cows will be delivered to Los Angeles, after sale, free of charge if desired.

2 Driving Horses.

Owners are dissolving partnership and quitting the dairy business, and every animal positively must and will go to the highest bidder. No limit or reserve.

Terms: 6 months time on sums over $50 with note and approved Security. Liberal discount for cash.

Don't miss this genuine closing out sale. Free Lunch at Noon.

ing eggs in water glass are given:

Use only perfectly fresh eggs. Stale eggs will not keep by any method of preservation. Clean out the vessel in which the eggs are to be packed (preferably a stone jar) by scalding with boiling water. Prepare the solution, using water that has been first boiled and then cooled to ordinary temperature.

To each 15 quarts of water add one quart of water glass. Pack the eggs into the jar and pour the liquid over them, covering the eggs completely. Do not wash the eggs before packing them, as this may injure their keeping qualities by removing a natural protective coating on the outside of the shells.

Keep the eggs packed in this manner in a cool, dark place, such as a dry, cool cellar.

Each day's gathering of eggs may be packed immediately after gathering by placing them in the jar and pouring over them just enough of the solution to cover them. This is better than to hold the eggs for several days at the risk of their becoming stale in order to have a sufficient number to fill the entire vessel at one time. In some of the warmer sections of the state, during the summer months, the temperature often rises high enough to start incubation in eggs. In such localities eggs must be packed soon after they are laid or kept in some cool place until they are to be packed.

Water glass is a somewhat alkaline liquid, but the diluted solution is not injurious to the hands, if they are dipped into it in packing successive gatherings of eggs, or in removing the eggs from the solution.

It is stated that eggs packed by this method will keep for some time (as long as four weeks) after they have been taken out of the preservative solution.

NOTES OF THE POULTRY YARD.

Noontime is the best time to feed the chickens raw vegetables such as cabbages, beets, and turnips.

Grain should not be fed oftener than twice a day.

Thousands of hens are killed every year by feeding too much wet food and mashes. The greater portion of the feed should be dry.

More satisfactory results are obtained from keeping only one variety than in having several, unless a person has plenty of patience and an abundance of room.

Charcoal in a granulated form should always be kept before fowls of all ages.

Large quantities of stale bread may be bought from a baker at 75 cents to $1 per barrel. Soaked sufficiently to soften, it makes splendid chick feed.

A hen should be fed some grain that she doesn't have to scratch for. Although exercise is necessary to keep her in good health, she needs time to rest and dust herself in the middle of the day.

In the damp, spring weather turkeys must be well protected from the weather. A good house is an open-front shed with a roost in the rear.—Farm World.

SCALY LEG.

Scaly Leg can be cured by taking equal parts of sweet oil and turpentine. Shake well and apply every two or three days. Keep this up until a cure is effected.

Thermal is experimenting in planting of dwarf milo.

Coulson's
POULTRY FOODS

Special Dry Chick Food

Makes Them Grow

COULSON'S SPECIAL DRY CHICK FOOD, during the five years it has been on the market has justly earned for itself its great reputation as a life-saver for little chicks by its special adaptation to their needs.

THE UTMOST CARE is observed in the selection of each of the dozen or more articles composing this unequalled feed; tender seeds, cracked grains blown free from dust, steel-cut oats, tiny pieces of dried meat and bone, willow and pure bone charcoal, are combined with other very necessary ingredients; every article being selected with special reference to its quality, strength, and desirability for the needs of the young chick.

FOR YOU TO BUY the many different articles composing Coulson's Special Dry Chick Food is quite impracticable; you could not be certain as to their quality for one thing, and the high cost of certain of them when purchased in small lots might lead to their being left out to the detriment of the chick.

TO MAINTAIN the high reputation of COULSON'S SPECIAL DRY CHICK FOOD, nothing is left undone to make it absolutely the best feed that can be made for the little chicks.

COULSON'S SPECIAL DRY CHICK FOOD can be fed exclusively to your little chicks for the first six weeks, at a cost of about four cents (4c) each; and what is of still greater importance, it will do all that can be done in the way of feed to bring them through that critical period of their lives in full health and vigor.

TO RAISE EVERY CHICK you hatch; to have fine, large, healthy chicks; to have chicks that will stand up and crow when eight weeks old; to raise chicks that you will be proud of, FEED COULSON'S SPECIAL DRY CHICK FOOD, THE LIFE SAVER.

POTATOES FOR FOWLS.

When digging potatoes, artichokes, or other root crops, store some in a place easily accessible and do not forget to give your fowls the benefit of them.

The poultry needs something bulky and succulent to take the place of the tender grass and other green vegetation on which they have been feeding for months.

Remember an exclusive grain ration is too concentrated.

Give them something "filling" for a change and see how they will enjoy it. Variety is spice for hens as well as humans, and healthy flocks are the result if this truth is kept in mind, and incidentally we might say—healthy fowls fill the egg-basket.

SKIM MILK FOR HENS.

In a recent experiment on the use of skim milk with hens, by the West Virginia Experiment Station, it was found that one lot of hens thus fed increased their egg production practically one egg for every quart of skim milk they received. It will be easy for any man to make his reckoning from these facts.

The reason why table scraps are so much recommended for chickens is because it is a balanced ration. The chickens like it because there is a variety of food in it. Meat, bread, vegetables, everything necessary for egg-production. If plenty of table scraps could be procured no better feed could be found for poultry, but the supply is restricted, of course, and only a few fowls can be benefited therefrom. If, however, poultry raisers would try and vary the food that they give their fowls in conformity to the ingredients found in table scraps, it would materially increase the contents of the egg-basket and redound to the health of their flocks. It is the one steady diet of corn, corn, and nothing but corn, that palls on the appetite of the farmer's fowl and causes the egg supply to fall off.

The right side of the question is to take things slowly. Work an apprenticeship with this the same as with any other business, and graduate with the full honors of a master. A few hens are the best in the beginning, gradually increasing in the work as your knowledge increases in the business. This is the same way to do things with poultry, and the better you lay your foundation, the greater will be your success.—The Feather.

There is no excuse for the filthy, ill-smelling yards and houses, and where these are found they are an evidence of laziness or neglect upon the part of the owner. There is nothing tedious or laborious about the work, but there are little things that must be done daily, and if these are done at the proper time, the fowls need not be anything other than a pleasure and a profitable side line.

The right of the farm poultry to recognition is indicated by the fact that in 1899 the total value of the barley, rye, buckwheat, broomcorn, rice, Kaffir corn, flax, small fruits, grapes, all orchard products, sugar-cane, and sugar-beets raised in the United States, as reported by the census, was less than the earnings of poultry.—F. D. Coburn.

Polly Oil

February 6, 1909.

Dear Sirs:—

I have used your Poultry Tonic for a long time and think there is none so good. But you have one remedy, POLLY OIL, I do not feel you know its worth. I had one little sample bottle given me a few weeks ago. I used it on two cases of swell head and it stopped the swelling right away. I had one pullet on which the lump had stayed for over two months, her bill having grown crooked, but as she was a pet I could not have her killed, but could not drive the lump away until I got the sample of Polly Oil. It then commenced to go away, and in a few days it was nearly gone. I have cured every one since that showed any signs of such trouble. I have used all I have and do not want to be without it.

Very respectfully,

FANNIE L. E. WEBBER,
Pasadena, Cal.

If not sold by your dealer send the price, 50 cents, and we will send you a bottle, prepaid. WEST COAST MILL, Los Angeles, Cal.

HOW TO BLAST BOULDERS.

THERE are three generally approved methods for blasting boulders with dynamite. The quickest and most expensive is to place the sticks on top of the boulder, preferably in some depression of the surface, if one can be found, prime with cap and fuse, place several shovelfulls of mud on the dynamite and fire. For a boulder five feet in diameter, the charge would be any number up to ten sticks of 50 per cent dynamite. This method makes much noise, and is unsatisfactory unless the boulder is somewhat flattened in the first place. A round, hard boulder is almost impossible to "mud-cap," as this method of using explosives is called.

Another way is to drive several holes under the boulder with a crowbar, place a stick or so in each hole, use electric exploders to prime the dynamite, and fire the charges all together with a blasting machine. This is the method commonly employed by professional rock-and-stump blasters, or by farmers where such supplies can be had. This method takes less than half the dynamite required by the first method. It is possible, when the boulder has a flat bottom, to make one large hole under it, put the charge all in the one hole, and fire with cap and fuse.

The best way, and the cheapest, is to drill a hole in the boulder an inch in diameter, and about a third of the distance through the rock. Load this hole about one-third to one-half full of dynamite, put a blasting cap with fuse attached into the dynamite, being careful not to allow the fuse to get in contact with the dynamite, fill the rest of the distance with moist earth, tamp it carefully by hand (never with a hammer if you wish to live), and fire. This method takes only about a tenth of the quantity of dynamite required by the first method. A boulder five feet in diameter, drilled 16 inches deep and loaded with a stick of dynamite as described, will be broken up well every time, no matter how hard and tough it may be.

Out-cropping rock can only be blasted out by drilling holes in it and firing as above described. Electric exploders and battery will be of the greatest value for this kind of work, as many holes can be fired together, and you get the benefit of their united strength. The holes should be drilled to a depth of a little below that which it is desired to plow.

Don't cut the fuse so short that the charge will fire before you have time to get out of the way, never less than 18 inches. In firing electrically, use enough wire to allow the operator to work the battery from a safe place, and don't forget that the charge explodes the instant the battery is used —there is no wait and no time to get away; so have it in a safe place to begin with.

For hard boulders and out-cropping rock, the stronger the dynamite the better. Low-freezing dynamites are good as they do not freeze so easily as ordinary dynamite, and thaw more quickly. Don't try to use frozen dynamite—thaw it first. Write to the manufacturers for directions for thawing, if you have not had experience in doing it yourself. The most progressive manufacturers of explosives get up special farmers' catalogues containing full and explicit directions for blasting stumps and boulders, and handling and thawing the dynamite, which they are glad to send to responsible parties.

Dynamite is also useful about the farm for a number of purposes besides taking out stumps and boulders, such as digging post-holes, sinking wells, excavating for foundations, etc. Progressive farmers are finding out more uses for it every year. Handled intelligently, it is a perfectly safe and exceedingly valuable part of the up-to-date farmer's equipment.—Country Gentleman.

"CHINOOK" WIND.

In its present acceptation, a "chinook" is the equatorial trade wind that blows during the winter months from the southwest and, laden with moisture, strikes the Pacific Coast from the northern boundary of California to the Alaskan archipelago. It is now the local name for the soft, balmy, south wind.

But it is a misnomer. In early days in Oregon and even as late as the early '70's, our summer wind from the northwest was called a "chinook," so named because it blew into the Willamette Valley from the coast region inhabited by the Chinook Indians north of the entrance of the Columbia. Among the pioneers and their descendants, a chinook wind was a "clearing up" wind. Now it signifies precisely the opposite; i. e. a wind from the south, followed by rain.

Within the past twenty-five years the word has been grafted into the speech and the written language of vast territory east of the Cascade Mountains and circulates freely throughout Wyoming. It has been carried into Western Nebraska. In recent years it has crept into Boston newspapers with local application. Any soft, balmy wind that springs up in winter is called a chinook.

Thus we see, in an age of high civilization and universal knowledge, the vicissitudes of written words. Within thirty years "chinook" has been turned "end for end."—Portland Oregonian.

DARK PHILOSOPHY.

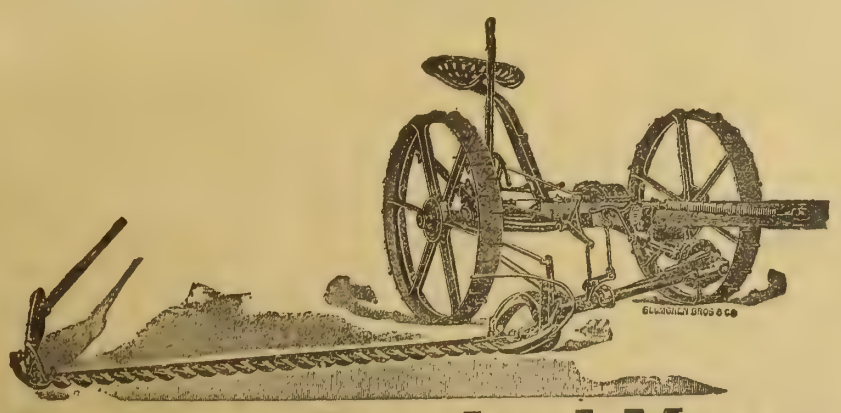
"A man kin allus fix up arguments to quiet his conscience," said Uncle Eben, "but 'tain't no use. No matter how much you turns de clock back, sundown gwinter come jes' de same."—Washington Star.

At Charlie's birthday party John conducted himself with a propriety that would have surprised his mother, while the little host behaved shockingly. "Charles," said his mother at last in despair, "just see how prettily Johnnie behaves. What will he think of you?" "Never mind, Mrs. Jones," John said loftily. "He's only trying to show off. That's just the way I act when I'm home."

A FRICTION STORY

A small boy can slide faster down a smooth, greased board than he can down an ungreased board full of slivers.

MORAL: A mower which comes closest to eliminating friction will require the least power to operate.



The New Standard Mower

The Cutter Bar is curved when raised, so as to be mathematically straight, to form a frictionless channel for the knife, when lowered. This Bar is patented and can be used only on the New Standard Mower.

The entire weight of the Cutter Bar is transferred through the Suspension Spring to the main wheels. The bar is carried —overcoming the friction of a dragging bar which is pulled or pushed on the ground.

Steel Rollers and Steel Balls surround the main shaft and pitman shaft.

The New Standard Mower develops more cutting power from its special high speed gearing and the grip of the main wheels on the ground than is developed in any other mower—although less power is required to operate it on account of absence of friction.

A folder giving full detailed description of the New Standard Mower and our other Haying Tools will be mailed free on application.

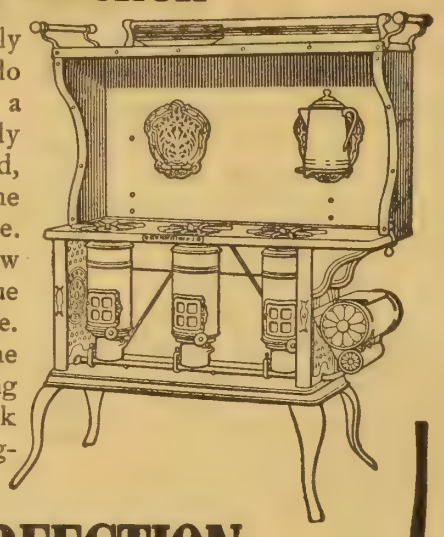
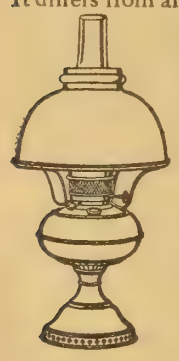
Put This Stove in Your Kitchen



It is wonderfully convenient to do kitchen work on a stove that's ready at the instant wanted, and out of the way the moment you're done. Such a stove is the New Perfection Wick Blue Flame Oil Cook-Stove. By using it you avoid the continuous overpowering heat of a coal fire and cook with comfort, even in dog-days The

NEW PERFECTION
Wick Blue Flame Oil Cook-Stove

is so constructed that it does not add perceptibly to the heat of a room. It differs from all other oil stoves in its substantial CABINET TOP, with shelf for warming plates and keeping cooked food hot, and drop shelves for holding small cooking utensils. Has every convenience, even to bars for towels. Three sizes. With or without Cabinet Top. If not with your dealer, write our nearest agency.



The **Rayo Lamp** is the ideal lamp for family use—safe, convenient, economical, and a great light giver. If not with your dealer, write our nearest agency.

Box H, Irvington, Cal.

Queries and Replies

Questions to be answered in this department should be received at this office one week before reply is expected. Write plainly on one side of the paper and sign full name and address. Unsigned communications receive no attention.

Japanese Iris.

We are considering the culture of Japanese Iris on a commercial basis, for the wholesale cut flower market. Will you kindly advise regarding the culture of this flower—when to plant seed and bulbs, and what demand there is for the bloom in the flower market.—L., Santa Cruz.

Gardeners who are growing it say that the principal requirement is to excavate and line the bottom of the excavation with clay or soil which will retain moisture, this is packed after which the garden soil for the bulbs is placed in it and they are kept supplied with abundance of moisture and never allowed to get dry. It has further been suggested that possibly a long furrow through which water could be kept running at stated intervals would keep the soil thoroughly moist. This flower grows best on the banks of small streams. Have any of our subscribers experience with these bulbs?

Leaking Milk.

I saw in recent issue of the Cultivator reply to El Monte subscriber as to remedy for leaking milk. I wish to say that I have had experience along that line, so that I can give you the result of my experience. At milking time I milk the cow perfectly dry, then rub the points of the teats with fluid extract of witch hazel.—L. G. J., Chula Vista.

The above is surely a most simple and harmless remedy and well worth the trial of our El Monte or other subscribers.

Inflamed Udder.

If your San Bernardino subscriber, who has a cow with a swollen udder will give 15 drops of fluid extract of poke root in bran mash once a day for three days and then skip three days and give again, it will probably help her.—L. G. J., Chula Vista.

Irrigation.

Which is the best method in this locality of irrigation? That is, flooding or the furrow system. If the flooding is the best what time and how often? How late can prunes be irrigated without hurting them.—W. N. S., Hollister.

It will be impossible to give explicit answers to the above questions, for the reason that varying conditions and crops require different treatment. From the last part of the question, we assume this is in a prune orchard, in which case probably the best method would be the furrow method. It is the custom to lay four or six furrows between rows, allow water to run for several hours until saturation of ground is given. The furrow method leaves the surface soil in much better condition than the basin system. The prunes should be kept in good growing condition up to ripening time. As to irrigation injuring them, we do not think that would be the case, excepting where irrigated up to ripening time they would be softer and also dry away more.

Oregon-Washington.

How can I get best condensed description of climate, topography and products of Oregon and Washington. C. L., Burbank.

Write the Chamber of Commerce at Portland, Oregon, or Spokane or Seattle, Washington.

Canaries Eating Eggs.

Seeing the inquiry and answer to the Capay subscriber in a recent issue of the Cultivator, I give the following from my experience with these birds. I have raised canaries for many years, the "English Norwich," but never had such experience as your subscriber suggests. I have many females laying now and am destroying their eggs as I am giving up the business As to what feed may correct the habit of their eating eggs, would say that at this time of year I boil fresh eggs hard and chop very fine, shell and all together with a couple of soda crackers and roll all very fine, mix with a quarter teaspoon of best cayenne pepper; feed of this each morning in addition to their bird diet. They never leave any of this mixture and I have found the birds thrive well on it. I give a little green food as well, and think you will find this a remedy for the egg eating. —Mrs. A. A. Henry, Rumsey.

The management of the dairy department at the State Farm at Davis conducted its first butter test at the State Farm, offering $230 in premiums. Much interest was manifested and it is expected the next test will bring out a greater number of exhibitors.

New York papers report that most of the hold-over dried fruit stock has been cleared off the market.

THE IMPLEMENT BLUE BOOK.

The Implement Blue Book, a 460 page volume, weighing two, pounds, listing and describing every agricultural implement, wagon, vehicle and automobile made in the United States, together with the name and address of the Manufacturer, is published by the Midland Publishing Co., Midland Building, St. Louis, Mo., exclusively for the dealers, at $2.00 per copy. The publishers have several hundred copies of the 1908 edition on hand which they agree to send to subscribers of this paper, who will send 20 cents to pay for packing, postage, etc.

BEAUTIFUL CATALOGUE.

The recently issued catalogue of Howard & Smith Nursery Company, 849 South Olive St., Los Angeles, is a work of art and full of information as well as beauty. The illustrations are all specially made for this catalog and are from nature. Especially striking is the front cover with illustration of Hybrids of Delphinium Belladonna and the back cover has a remarkable illustration of Bougainvillea.

Veterinary

Answers in this column by Dr. R. T. Whittlesey, are without charge. For immediate mail answer remit $1.00. In writing questions give full symptoms or particulars of injury of animal.

Swelling on Ankle.

I have a colt that received a severe cut on one of its hind legs. While the leg was sore it threw its weight on the sound leg, with the result that it injured the ankle on the sound leg; it has been so over a year. The ankle is somewhat enlarged but not a great deal. What shall I apply to reduce the swelling, which no doubt comes from the bone; would a blister be advisable?—C. J., Laton.

If the horse is lame in the ankle blister it with Gumbault's caustic balsam; if not lame, you will get better results from a tight bandage. Saturate a layer of absorbent cotton with glycerine and lay next the skin, then bandage over it as tight as you dare to do.—R. T. W.

Sore Shoulders.

My six year old mare's shoulders become rough or have pimples about the size of a half marble and gradually get so I am compelled to stop working her. After several weeks rest the same condition returns when doing only moderate work. I have tried new pads; also new snug fitting collar.—J. C. P., El Monte.

Advise the use of a strong solution of white oak bark, as follows: One-half pound of bark in one gallon of water. Boil a few minutes. Add about equal parts of alcohol and rub the shoulder once or twice daily.—R. T. W.

Heifer Shy of Milk.

I have a heifer which I have been milking four months—this is the second calf. Has given a good quantity of milk up to within three or four days ago when she discontinued suddenly and since have only been able to get what milk would barely cover bottom of bucket. She eats well, has fine grass pasture, and also chews cud. I thought she might be a self-milker. One night tied her up very short but next morning got no milk. Bag is very limber. What can I do to bring her to her milk—E. W. R., Watsonville.

Cows will frequently let up in the quantity of milk from indigestion and it will usually return in a few days to normal amount.—R. T. W.

Discharge.

Have a mare seven years old that discharges blood at intervals from vagina. She is spirited and works well and has good appetite. Am feeding alfalfa hay and barley. What is the cause of this, and is there a remedy?—Subscriber, Anderson.

There is probably some growth, wart or tumor in the vagina or uterous. An examination with the hand will probably reveal its nature and location. Such growths if not too extensive can usually be removed with an eccrassour.—R. T. W.

DR. WHITTLESEY'S VETERINARY REMEDIES.

These are not ordinary mixtures but are from well tried formulas, used in an extensive practice in Southern California for nearly a quarter of a century. Dr. Whittlesey's Sulphur Arsenical Salve for deep fistulous or ordinary chronic, indolent sores such as, "Poll Evil," "Fistulas," "Quitters," "Thrush," "Scratches," "Warts," "Collar sores" or "Sit-fasts." $1.00 per package postpaid. Printed directions. Dr. Whittlesey's Antiseptic Healing Powder. Forms a coating over raw surfaces, excludes air, flies and floating germs. Makes a cheap and convenient dressing for the many sores that occur to stock on the ranch. $1 full pound can postpaid.

DR. R. T. WHITTLESEY.
Veterinary Hospital, 714 East Seventh St., Los Angeles, Cal.

Wood soled Boots and Shoes. Boots $3.25; Shoes, $2.00 O. J. Weber Co., 225-227-229-231 East Sixth St., Los Angeles, Cal.

This Great World History
SENT TO YOUR HOME FREE

Just send your name and address on the coupon below—that is all you need to do. It does not cost one penny and as soon as your name and address is received a set of the world famous **Library of Universal History** will be sent to you prepaid.

HERE is the greatest opportunity ever offered—an opportunity for our readers to secure at less than half price these fifteen beautiful volumes all printed from large new type, embellished with over 100 double page maps and plans, 700 full page illustrations, many of which are in colors, and over 5,000 pages of reading matter.

This offer is made possible by the failure of the publishers, the Union Book Co. of Chicago. Hundreds of sets of this work have been sold at $60.00 each and they are worth every cent of it, but we now name you a rock-bottom bankrupt price of only 50c after examination and $2.00 per month for 14 months. It is impossible to name a lower price for cash in full, as this is less than half the publisher's price and is made only to close out the few remaining sets quickly.

Before you decide to buy we invite you to examine this work in your own home for an entire week absolutely free of charge, and should you not want the books after examination we will have them returned at our expense. **We earnestly request you to examine this Library;** let your wife and children and friends see it. No better set of books could be placed in the hands of children than this; it reads like a thrilling novel, and is in fact a complete connected History of every country, nation and people from the beginning of time to the present year; the **greatest World History ever written** and endorsed by scholars everywhere.

Prof. George Fellows, of Indiana, says: "Most histories of the world are dreary compilations. This work, however, is clear, interesting and accurate."

Ex Vice-Pres. Stevenson says: "It is a complete record of the human race and should find a place in every Library."

E. Benjamin Andrews, Chancellor of the University of Nebraska, says: "Its educational value in the home is sure to be very great."

Rev. Frank W. Gunsaulus, of Chicago, says: "These volumes will be of immense service in stimulating history study in our country. It is a work of real genius."

Prof. Dabney, of Virginia, says: "Southern readers will be gratified at the impartial spirit in which the war for Southern independence is treated."

The St. Louis Globe Democrat says: "This work invests the study of History with a new charm that will be felt by both young and old."

NEVER BEFORE in the annals of the publishing business have we seen such a bargain. We do not hesitate to recommend this offer to every reader of this paper; indeed we believe every family should own a standard World History, for by knowing how other countries than ours are governed it gives us a better knowledge and higher appreciation of our own system of government and makes us better citizens.

We will be glad to give you an opportunity to see for yourself and make your own decision after you have seen the beautiful binding, the magnificent illustrations and have read parts of this great History of man on earth. Then you can decide. Should you not wish to keep the work you will notify us and we will have it returned at our expense.

The illustration of the books given here does not do them justice; you must see them to realize what they are. You assume no obligation to us or any one else by making this request, you simply **ask for a free examination** in your own home without paying any one anything, and remember you can send the books back at our expense, and remember, too, this bankrupt rock-bottom price of $28.50 for this $60.00 Library has been made possible only on account of the failure of the Union Book Company, thus necessitating a receiver's sale at a price which barely covers the cost of the paper and binding.

MAIL THE COUPON

15 Massive Volumes

Each volume 7 inches wide and 10 inches high; weight, boxed, nearly

75 lbs.

Here is Our Offer: Once more we wish to make our offer perfectly clear. Just write your name and address on the coupon, cut out and send it to us and we will have this Library sent to you for free examination in your own home for an entire week. No mere description will do this History justice. You must see the large new type —the complete set, the beautiful binding, paper and illustrations; the large new type and read parts of the work itself. Then if you don't want it just notify us and we will send for the books at our expense. To own this work costs you only 50c down and $2.00 per month for 14 months—no more—and remember you get a regular $60.00 set of books for only $28.50 on easy terms or cash, if desired. This is our rock-bottom bankrupt price and the greatest book bargain ever offered to the readers of this paper. Use a postal or letter if you wish, but the coupon will do. **Send us no money.**

Address American Underwriters Corporation, Dept. 235 , 240 Wabash Av., Chicago

We employ no agents. We send the books—not misleading sample pages—MAIL THE COUPON.

Bees and Their Care

TROUBLES OF A BEE-INSPECTOR.

THIS is a subject that is rarely touched upon in the columns of any bee-journal, and it may appear to be a little out of the ordinary to present some of the following suggestions to intelligent bee-keepers; but I am of the opinion that Gleanings numbers among its subscribers not a few parties who have no knowledge of bee-diseases, being so ignorant of this important subject that they lose their bees by one disease or another, and never guess the cause.

In my experience as a bee-inspector I find parties who question the existence of bee-diseases, and it is a hard job to convince them that they are wrong, as it usually occurs that a person so ignorant as to question the existence of a contagious disease among bees is conceited, and all of the evidence brought to bear is of no avail. The best way to convince such people is to bring action against them in the court; for, although they may not be convinced they can be convincted of violating the law, and, after once being compelled to pay for their stubbornness, they will yield to the wishes of the inspector on the next occasion. I do not advise indiscriminate prosecution of any one; but when it is necessary I believe in penalizing to the limit. It is folly to let any one maintain a position whereby he disputes facts, established by scientific analysis made in our government laboratories by qualified men who devote their energies to the study of just such diseases.

A bee-inspector is often placed in very embarrassing circumstances. A person capable of fulfilling the duties of inspector should be a competent and well-informed bee-keeper; therefore if he is an apiarist, owning bees near where his services are required, he is placed in a position whereby he can be accused of using his authority to further his own interests. For instance, if it is necessary to destroy some colonies, the owner at once takes this view. Of course, this accusation is fostered solely by parties who are either ignorant of the consequences of the disease when left to itself or by those who are trouble-makers. I have confidence in mankind enough to think that, where the inspectors are apiarists, with the right kind of feeling toward this great and interesting industry, not one in twenty will be found who is doing this inspection for the material benefits derived. An inspector who does his duty is sure to find opposition. In all civilized countries we find neighbors who do not get along together. Sometimes each of these two parties owns bees in an infected district. The inspector may find one apiary contaminated, and order it destroyed, while the other is in splendid condition. This at once leads the first to accuse the inspector of being partial in his methods. Of course, circumstances like the above are rare, but still they exist.

In my opinion the worst hardship the inspector is confronted with is the enforcement of the law when opposed by some influential person. It is not a pleasant duty to start proceedings or legal action against an offender of the statute, as it necessarily calls into court parties as witnesses who rather shrink from the duty, thinking that, perhaps, they may create an enmity with the one they testify against, as often happens.

If any party owning bees does not know the character of the disease supposed to exist in the hives, and after an examination by the inspector still doubts or questions the ability of the inspector in determining what is wrong, and requests that he be allowed to retain a sample of the diseased comb to submit to the government experts for an analysis, he immediately blocks any possible attempt of the inspector to do him an injustice. This kind of test would at once vindicate or convict the inspector of unfairness; and it is not expensive nor unfair to the inspector. I for one gladly submit to such a test. There is a possibility that, in some cases, it might be unfair; but in most instances I believe that it would be of material benefit to the inspector; for, after a few such tests, it could easily be shown that the inspector is either using unlawful and malicious methods or giving a square deal.—Gleanings in Bee Culture.

APICULTURE AT THE UNIVERSITY

We are interested in observing the general movement in the direction of apiculture in our agricultural colleges and experiment stations. This subject in the University of California was first taught during the academic year of 1893-4, and since that time it has formed a part of the regular instruction in this institution. The present instructor in entomology in charge of apiculture came in touch with the work in California in the spring of 1905, when serving as Assistant in Apiculture in the Montana Agricultural College, where, under the direction of the entomologist, he has been in charge of the teaching and experimental work in apiculture since the year 1901.

The past three years have witnessed a distinct advance in the amount and scope of the work being done in apiculture. The number of courses offered, from two repeated twice a year, has been augmented to seven, three of these being repeated twice a year, and two being capable of election indefinitely without repetition of work as research courses. The distinctly apicultural courses are now announced separately from entomology, giving apiculture a recognition and permanence co-ordinate with entomology as a sub-department under agriculture such as has never before been given to this subject in any institution of higher learning in America. It is now not only possible for a student to get his B.S. degree in apiculture, but increased facilities are being provided for research work looking toward higher degrees for those qualified for such studies.

The university apiary numbers forty colonies, and has representatives of each of the six varieties of bees of economic importance. There is now available equipment for thorough instruction in comb and extracted honey production, wax production and manipulation queen-rearing operations, and bee disease investigations. Apiculture will from the first form a part of the school work on the university farm at Davis, where instruction is to be begun this winter. In connection with this instruction work on the farm there is to be established a well-appointed experimental apiary with an apiarist in charge. There are also three out-apiaries with the owners of which the university has made arrangements for co-operative tests of methods of practice and varieties of bees on a more extensive scale. Arrangements have been made with several more of the larger commercial apiaries of the state for advanced students to spend their summers in practical experience in apiary management.

Whether this work of the past fifteen years, culminating in the more recent rapid advances, is to be permanent or ephemeral, as has been the case in every other institution in this country where apiculture has received attention, remains largely with the bee-keeping public. The authorities have been responsive. This has been true in some instances elsewhere. But there seems to be a normal limit to the amount of work that state institutions are willing to do in these untrodden lines, without precedent merely upon the suggestions and recommendations of those personally engaged in the work. The rank and file of bee-keepers must plead their case incessantly and concertedly if they would finally triumph.—Ralph Benton in Gleanings.

An Easy Turning Wheel Pays Best

When you're studying ways to increase business—how to make more trips per day, or how to carry more pounds per trip—remember

MICA AXLE GREASE

It puts good dollars into many a pocket by saving wagon-wear and horse flesh.

A little on each wagon spindle puts "go" into a whole week's business.

In the High Sierra

THE Mount Goddard quadrangle, in California surveyed during this past season by topographers of the Geological Survey, comprises 40 miles of the crest of the Sierra Nevada. Though difficult of travel, the region can be reached by one day's horseback ride from Bishop or two days' ride from the lumber town of Shaver, on the opposite or west side of the divide from Bishop. The general topography of the Sierra shows an inclined plane running from the San Joaquin Valley 100 miles to the crest, at an elevation of 13,000 to 14,000 feet, and then dropping away abruptly on the east side from 6,000 to 10,000 feet in a distance of 10 miles.

It is up the smoother sides of the mountain that the topographical surveyor endeavors to climb to make his stations on the topmost rocks. When such a gentle, sloping mountain side is found he is profoundly thankful, for some of the ascents are almost perpendicular.

"Within 2,000 feet of the summit of most of the peaks, was as near as it was possible to approach on horseback," said topographer George Davis, in charge of the Government party engaged on this survey. "The rest of the climb had to be negotiated afoot."

Very few roads exist in the Mount Goddard country, but there are numerous trails. Some are straight and afford good going; others are so steep and rough that to take a pack-train over them is next to impossible. Some are well blazed by the characteristic cuts on trees, others by rocks piled upon another; but in most cases these rock-piles or "duck blazes" of the cattle or sheep men have been demolished by the winter snowslides.

"In moving the camp to the head of Bear Creek," said Mr. Davis, "a peculiar trail was encountered. For some distance the blazes on the trees were well cut and regular, although the traveling became rougher and rougher. All the members of the party were praising the kindly trail blazes when suddenly they ended at an impassible cliff; likewise the trail. At the foot of the cliff, however, was a tree with the same old blaze, which appeared in the shape of a diamond, while above it was an artistically carved hand pointing straight upward. We found it advisable to disregard this last sign, and proceeded on our way by another route.

"Meadows in this region are plentiful and are generally located in canyons and glaciated basins, and those that have not been over-grazed by sheep and cattle afford good pasture. Adventurous inhabitants of Fresno, on the west side of the divide, and of Bishop on the east side, as well as the cattle and sheep herders, take advantage of these picturesque spots for summer camping places. Large game, however, deer and bear, are not so plentiful in the Sierra as in the Coast Range, and fishing is limited to certain localities. We had the pleasure of meeting several parties of lovers of outdoor life."

The difficulties and annoyances of the topographer while working in high altitudes are varied. Often he is compelled to climb the same peak two or three times on account of fog, rain and snowstorms, which often have a provoking way of rising just after the ascent is completed and effectually preventing long sights. "Nearly every day last summer," said Mr. Davis, "generally after an oppressive heat in the valley heavy, threatening clouds gathered around the peaks and at about 2 or 3 o'clock in the afternoon formed thunder clouds of tremendous proportions. The lightening often struck in too close proximity for comfort; but outside of scaring the stock, no trouble resulted. One amusing electric phenomenon occured while the party was occupying a station on Mono Pass. Sinister black clouds had been gathering for some time and at last they broke with the usual fury of thunder and lightening. Work became impossible and while preparing to descend to the point where the mules were tied we noticed repeated buzzing sounds uncomfortably close. We proceeded to experiment and found that by stretching out our hands we could induce the peculiar vibrating sound on the ends of our fingers and especially on the end of the tripod, which seemed wonderfully conductive. The electricity seemed to play between the long ears of the mules, making the management of the animals very difficult. At various times during the season we saw huge boulders of rock, for no apparent cause, fall from great heights thousands of feet below, crashing and reverberating like cannon explosions and raising immense clouds of dust.

"Visitors to the Sierra should enter in June and July. After the 1st of September, it is safer and more comfortable to stay away from the mountain region, for the cold and wet season is then at hand. Our party encountered five snow storms in September, and every morning during that month the streams and lakes were frozen hard."

If you raise grain, why not own a fanning mill? It will pay for itself in one season. There is always some grain that needs cleaning or grading before it is ready for the market or for seeding purposes, and the fanning mill is the machine that will put it in condition.

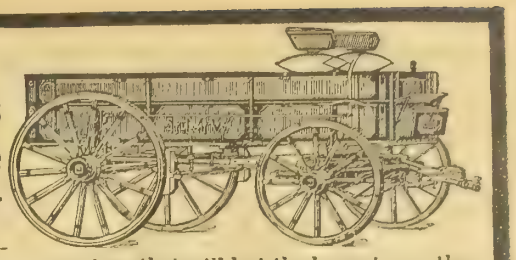
Orchardists at Lewiston, Idaho, will plant 100,000 fruit trees this spring.

LARGEST VEHICLE FACTORY IN THE WORLD

Studebaker

THE STUDEBAKER PLANT COVERS 101 ACRES

Means Genuine Economy



The first cost of a vehicle or a set of harness is one thing—the yearly cost is another. You want the farm wagon or buggy or carriage that will last the longest, run the easiest, require fewest repairs and, while costing no more in the beginning, will *cost a great deal less in the end.* That's the only *genuine economy.* The Studebaker Bros. Mfg. Co. have built up the largest vehicle and harness business in the world—*solely by saving money* for its customers. If you are looking for a *real* bargain—one that will give you *years* of satisfaction—

See the Studebaker Dealer and let him show you why the *Studebaker lasts* so long, gives such good service, runs so easily and costs so little in the end. MAKING A GARDEN.

(Continued from Page 377.)

tionately large, but all tended to coarseness.

In the boxes and barrels when the guano manure-water was used the second time the flowers were beautifully fine and wonderfully luxuriant. The fences and a rough trellis that concealed the outbuildings were a mass of foliage and blossoms. The trailng plants completely covered the woodwork of the boxes and barrels, and the earth was concealed by growing plants. The rock pyramid was not recognizable, being hidden by a mat of flowering verbenas, some single plants of which covered an area of three or four feet square. Almost every northern species of annual flower was to be seen in full bloom—stately gladioli, white and scarlet phlox and yellow nasturtiums; masses of blue lobelia, petunias, asters, begonia and every variety of fuchsia or geranium.

The Humboldt county creameries at the last pay-day gave the following prices for butter fat delivered: Eel River 39c, Grizzly Bluff 39, Pioneer 39, Central 38½, Capital 38½, Cream City 38½, Ferndale 38½, Riverside 38½.

How many persons are aware that it was Edwin Booth, the brother of the assassin of Lincoln, who saved the life of Lincoln's eldest son? The details of this extraordinary occurrence are given authoritatively in the April **Century**. The number contains four Lincoln articles of unique interest. Mrs. M. Helen Palmes Moss tells the story of how, within an hour, on the day of the shooting, she shook hands with both John Wilkes Booth and the President; and Leonard Grover, manager of Grover's theatre, Washington, during Lincoln's presidency, has written entertainingly of "Lincoln's Interest in the Theatre." There is first publication, also, of two remarkable letters—Edwin Booth's on the President's assassination, written immediately after the event, and that of Miss Julia A. Shepard, now living in Ogdensburg, N. Y., written to her father two days after the tragedy.

POULTRY.

ONE PRAYER.

Let me work and be glad,
O Lord, and I ask no more;
With will to turn where the sunbeams burn
At the sill of my workshop door.

Aforetime I prayed my prayer
For the glory and gain of earth;
But now, grown wise and with opened eyes,
I have seen what the prayer was worth.

Give me my work to do,
And peace of the task well done;
Youth of the spring and its blossoming,
And the light of the moon and sun.

Pleasure of little things
That never may pall or end,
And fast in my hold no lesser gold
Than the honest hand of a friend.

Let me forget in time
Folly of dreams that I had;
Give me my share of a world most fair,—
Let me work and be glad.
—Theodosia Garrison, in Independent

BACHELOR AND BABY.

I AM a bachelor with a peaceful disposition and a bald head. My state of single blessedness and my baldness are my misfortune, not my faults. Various girls are to blame for the first, and unremitting application to novel reading in bed may have something to do with the latter.

Like the traditional spinster, a bachelor is authority on the rearing of children, and I have often expressed my views on the subject at some length to a sister of mine who is married and has a small daughter aged five. It so happened that I have seen little of the child, as my hours for calling on my sister are late, and when I arrive Grace; the little girl, is usually in bed.

But the other day my theories on the training of children received a severe shock. My sister said to me: "John, Robert and I have an invitation to visit a friend of mine for the week end. She lives out of town and if we go we don't want to take Grace with us. Now, I've often heard you say that you'd know how to bring up a child, and here's an opportunity. Suppose you come over Saturday afternoon and take charge of Grace until Sunday evening, when we come home?"

This invitation I accepted, although it meant giving up an evening at the club and dinner engagement on Sunday. I went over to my sister's Saturday noon, just before she left, ready for business. She said: "You won't have anything to do, John, except to keep an eye on her, and if you feel like it to amuse her, take her for a walk to-morrow or something of that sort. Maggie, the nurse, will look after her meals, put her to bed and all that; so I don't think you'll have any trouble."

Then she turned to Grace, who had been standing by her side, gazing at me with a wide-eyed stare common to children and which to my disgust made me feel somewhat uncomfortable.

"Grace," said my sister, "mother is going away for Sunday, and Uncle John is coming here to stay with you. Now, be a good girl and do what he tells you."

As she left the room I turned quickly to the child.

"Don't you want to play, Gracie?" I asked.

"Yes!" she responded with enthusiasm; "want to play horsie."

To anyone needing strenuous exercise I can recommend "horsie" as played by my niece or rather as played by her uncle at her direction.

Procuring a piece of string somewhat the worse for wear, she approached me and requested me to take it in my teeth.

"You dets on de floor," explained Grace, so down on my hands and knees I went. The equestrienne sat on my back, kicked me in the sides and pulled violently on the string. I crept painfully about the room, continually urged on to greater speed, until I finally stepped in the hall for rest.

My sister was a careful housekeeper, but my hands and the knees of my trousers showed the traces of their contact with the carpet. As I was examining them Miss Grace said: "Want to play horsie on de piazza, uncle John "

"O, no, dear," I expostulated. "It's cold outside and—" I stopped. Tears were gathering in her eyes and her lower lip was beginning to tremble.

"Very well, we'll go," I assured her, "but you must put on your hat and coat."

I assisted her on with her wraps and we went out on the "Pazazza." It was a clear, cold autumn day, and the sun was shining. A beautiful day for a walk. But I was playing horsie. Up and down on the cold piazza I crept, my hands and knees getting sorer every minute. I hadn't thought to put on a pair of gloves, and after two or three laps decided they'd be useless.

"You is a fat, slow horsie," remarked my rider as I started on what I determined should be the last lap of the circuit. Just as I reached the steps in front of the door Grace suddenly dismounted with a cry of joy and ran down the steps. I raised my head and there on the sidewalk stood the Only Girl, trying to repress a smile, while my rival stood by her side grinning malevolently.

I was a sight. My hands were black my trousers ruined, my hair was rumpled, the string which I dropped was tangled up in my collar and I was dripping with perspiration, cold as it was.

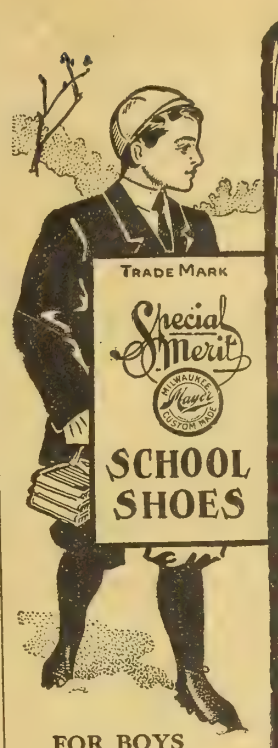
"You look warm, Mr. Blake," grinned my divinity with a smile.

"Having a hot time, John?" grinned my rival.

"My sister left me in charge of Grace," I explained, "and I am engaged in amusing her. This game is known as 'horsie.' It's a little bit strenuous."

They smiled and passed on while I told my niece that it was time to go in and that we'd play "horsie" again some other ady. When it came time for her to go to bed the nurse undressed her. I then picked her up and was about to deposit her in the bed when she reminded me she had to say her prayers.

When she began I felt sinful. When she finished I felt more so. After saying "Now I lay me," as fast as she could, she began her father and mother, all her other relations except me, her cat, her doll, the family dog, the cook and all the other servants. And she finished: "O, Lord, bress uncle John; put some hairs on his head an' make him pretty. Amen."



FOR BOYS *and* GIRLS

Mayer

"SPECIAL MERIT" SEAMLESS SCHOOL SHOES

SCHOOL SHOES without seams—think of it—*seamless school shoes!* They are strong and sturdy, have seamless uppers, tough soles and double leather toes. By far the most durable and lasting shoes obtainable.

TRADE MARK

The Mattress of Quality

In introducing our Kapokeen Mattress to the readers of The Cultivator, we are taking the first steps toward establishing a National reputation and market for an article, which, on account of its many advantages, has gained a pre-eminent position in its own vicinity.

"Kapokeen" is made from the Kapok or silk floss obtained from the bean of the Eriodendren tree, grown on the island of Java. It is prepared by our own patented process, which removes every particle of seed and preserves in full the resiliency of the natural fibre.

The mattress is made in our own factory where every precaution has been taken to insure absolutely hygienic conditions, by skilled workmen using only the best quality of materials throughout.

NOTE THESE POINTS.

Kapokeen can be "made over" in exactly the same manner as hair.

Kapokeen is sun dried, sun cured, and free from chemicals or other foreign substances.

Kapokeen, no matter how long it has been in use, by being placed for two hours in the sun, will expand and become as resilient as a new mattress.

Price *No. 1 Kapokeen Mattress, 4-4 size, 5 1-2 inch box, Imperial edge satin ticking* **$15.00**

Three-Quarter Size, $12.50 *Single,$10.50*

Kapokeen Mattreses are made only by

John Breuner Co

A postal will bring you a little booklet describing this mattress

Angle Lamp

The Light That Never Fails

Thousands in use all over the country. A good light is the greatest pleasure and the first necessity of every home.

The only lamp on the market that is sold under an absolute guarantee.

Remember, the light from Kerosene is the light science has agreed upon as being the purest and best, because it is soft and mellow and restful to the eyes.

Here are a few of The Angle Lamp Merits:

NO UNDER SHADOW. NO SMOKE, NO ODOR, LITTLE HEAT.

GREAT ECONOMY—COST LESS TO BURN than an ordinary lamp. As easy to operate as gas or electricity, and better than either. ABSOLUTELY SAFE under all conditions. Lighted and extinguished like gas. Burned HIGH or LOW like GAS without a trace of odor. And a BRILLIANT, soft, steady, shadowless light—but this you will have to see to appreciate.

The lamp as shown in cut burns 22 hours on 1 quarts of oil.

About the House

A little later in the spring our city friends will begin to think longingly of green fields and country cream and berries, and soon a letter will come to Country Mouse from City Mouse, so worded that if at all possible Country Mouse promptly replies with an invitation for a "nice long visit." This is all right and as it should be.

But this is only half of the right thing. Along next winter, when work is a little more slack on the ranch, a little bit easier to leave, then let City Mouse, remembering thankfully her pleasure of last summer, write to Country Mouse and gratefully urge her to come and pay a visit in the city at the time when the shops are full and stirring, when there are concerts and plays galore, when Country Mouse can be given the time of her life.

The second half is more apt to be neglected than the first half. But I don't think it is because city people are selfish or heartless, or indifferent. They are busy, and possibly careless; they mean to have Cousin Carry and that lovely Mrs. Peters visit them in their city homes, but there has been no definite time set and the good, honest, but weak-spined intention gets pushed back out of sight and forgotten.

What the sensible country woman should do is to tuck an additional sentence into her warm letter of invitation in the spring. Let her write as joyfully as the spirit moves her when she hears her friends or her kin are coming to visit her in July. And then let her add that she is especially glad of a chance to welcome them this summer as she hopes to be able, herself, to pay a visit to their city homes during the coming winter.

And then, next winter, when she is tired of muddy roads and the monotony that creeps into even the best loved homes at times, let her write a cheerful note asking if it will be convenient for her to visit the city friends at such and such a time, pack her best bib and bonnet, and go serenely away for her well-earned playtime.

And she will be welcomed heartily and honestly by a hostess only too glad to be reminded of her pleasant summer and to be saved from the assaults of her conscience which may otherwise mutter in the spring, "Now, you know you've said time and again you meant to ask Cousin Mary up for a little visit, and here the winter is over and you haven't done it after all."

To make "Hot Cross Buns" for Easter, dissolve one-half teaspoon of salt, two tablespoons of sugar and two of butter, in a cup of hot milk. When this is luke warm, add half a yeast cake which has been softened in a little warm water, and enough flour to make a stiff batter. Beat well and set aside in a warm place; when light, add a small half cup of currants, a little grated rind of lemon, a half cup of sugar, a heaping tablespoon of soft butter, two well-beaten eggs and enough flour to make a soft dough; knead well and set aside until it is light. Then mould into round biscuits and place in a well-greased baking pan. Let them rise and just before putting in the oven dip a sharp knife in flour and cut a cross in the top of each biscuit. Have a hot oven and when the buns are baked, brush the tops with sugar and butter and set back in the oven for a minute or two.

Chocolate crackers are dainties that are easily made at home. Take the little oblong oyster cracker, or the small square crackers, and be sure they are fresh and crisp. Put some sweet chocolate in a bowl and set it over the hot tea kettle. When the chocolate is melted drop the crackers in one at a time. Take out quickly and lay on waxed paper. The chocolate may be flavored with peppermint or wintergreen if you wish.—Elbepe.

WHY WOMEN HAVE NERVES.

Nerves belong particularly to those women who lead what might be called a strenuous life. Not so many women are afflicted who are living out their existence in a more humdrum fashion. Especially are nerves found among women who are employed in a business capacity. To begin with, the majority are criminally careless.

Women have been known to attempt and—more than that—to accomplish a hard day's work in an office on a cup of coffee and a roll for breakfast, and tea and toast or a cup of chocolate and a bowl of milk for luncheon. Frequently you have seen a party of girls making their luncheon on ice cream soda. They probably save their lunch money for ribbons and frills, but they expend ten times their value in vitality.

If a man tried living on that plan he would soon collapse physically, but there is no immediate danger of such a catastrophe, since men care more for their meals than do women.

Another reason for a woman's prominent characteristics is that she never shields her nerves. They are allowed to become too sensitive. If she misses a train she does not sit calmly and wait for the next one, as she might as well do, but she sits on the edge of the seat, taps her foot on the floor and is continually on the alert for the man with the big voice to announce that her coach is ready for occupancy. Then she will hurry as fast as ever she can for fear she will not be able to get a seat. She will contract her eyebrows, bite her lips and clinch her fingers and, perhaps, talk excitedly to herself all the time she is hurrying to the entrance gate, all the time using up her nervous energy instead of storing it up for a time when she may really be in need of it. Then, when the time of need does come, she is all worn out, and is ready to cry with vexation at the slightest thing that goes wrong.

How few women we see now that have that sweet placidity of countenance that is in their grandmother's pictures. Our manner is stamping itself upon our faces as surely as upon our constitutions, and many, many times it is just because we do not keep our stomachs properly filled with wholesome food and plenty of it. A girl had much better throw away her pride and take a good home lunch to her work in a basket than to depend upon such nerve-destroying elements as ice-cream sodas for her daily strength.

HUMAN NATURE'S WEAKNESS.

"I don't mind Mrs. Gigshaw making fun of the way I talk," said Mrs. Lapsling, forgivingly. "It's only her way. We've all got our little peculiarities and idionockrasies."

GREEN TEA.

The green tea is made from the same leaves as the black, although some varieties are best adapted to make each of these respective kinds. The green tea process is the same as that for making black tea, except that instead of withering from twelve to twenty-four hours and fermenting from three to six hours (when oxidation takes place, which renders it black) the green leaves are quickly brought in and placed in a covered double boiler—that is, a saucepan with a hot water jacket (one pound of leaf to a four quart boiler)—and allowed to remain surrounded by boiling water from seven to nine minutes; the cover should be removed and the leaves stirred at intervals. This will render the leaves very soft and flaccid, ready for rolling. During this rapid process the oxidizing agencies of the leaf are sterilized by the boiling water and steam in the hot water jacket surrounding the leaves, and the production of green tea is rendered possible. These flaccid leaves are rolled in like manner to the black tea for about ten minutes, being stirred at intervals until they lose some of their moisture and become sticky; then they are again rolled from fifteen to twenty minutes under all the pressure that can be applied. After rolling they are immediately placed in the oven in a pan and turned at intervals (similar to the black tea) until they are dry and brittle to the touch and a slight scent of tea is given off.—Tea and Coffee Trade Journal.

CHANGE IS REST.

Concentration and system are excellent qualities, especially in work. But overconcentration and overniceness in clinging to one settled rule tell on the nerves in the long run. Relaxation is the great principle that physicians are trying to teach women nowadays.

Recreation need not always consist of social diversion, of the theatre or of a shopping trip, although all are excellent in their way. But people must vary their routine. Men in business life usually have this variety, but nine women out of ten, especially housekeeping women, will go through the same round of duties and pleasure 365 days in the year.

If you begin to suffer from the depression, the despondency, that so often is the precursor of nervous breakdowns, seek a change of some sort. Do something that you are not accustomed to do. Get a flood of new thoughts and new ideas percolating through your mind, and before you know it you will be laughing at the idea of despondency from imagined illness or any other cause.

"ECLAW."

"I heard her boasting that her dinner party was a success from the beginning and ended with the greatest 'eclaw.' What's 'eclaw,' anyway?"

"Why—er—that was the dessert, of course. Didn't you ever eat a chocolate eclaw?"—Philadelphia Press.

A HINT.

"Yes," said the young student thoughtfully, "when I get interested in a subject I never stop until I have embraced it thoroughly."

"That's nice," was the hesitating reply. "Do—do you think I'm an interesting subject?"

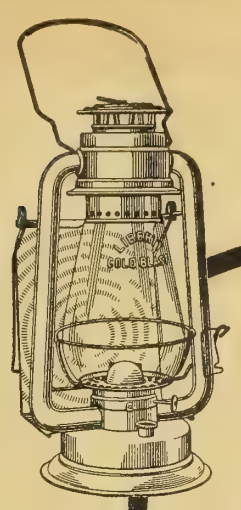
WHY TUMBLERS ARE SO CALLED.

How many times a day do we use words without stopping to think what they mean! Every day at luncheon and at dinner we drink out of a tumbler. But I, for one, never thought why the large glass that holds our milk or water was so called, until once upon a time I happened to have luncheon at All Souls' College, Oxford, where the curiosity of all the strangers present was excited by a set of the most attractive little round bowls of ancient silver, about the size of a large orange. These, we were told, were "tumblers;" and we were speedily shown how they came by their name.

When one of these little bowls was empty, it was placed upon the table, mouth downward. Instantly, so perfect was it balance, it flew back into its proper position, as if asking to be filled again. No matter how it was treated,—trundled along the floor, balanced carefully on its side,—up it rolled again, and settled itself, with a few gentle shakings and swayings, into its place.—Selected.

BEEF TONGUE.

Soak a fresh beef tongue in cold water an hour. Boil until nearly tender. Take out and skin; put aside until cold. Put in a saucepan enough stock to cover the tongue. To this add a teaspoonful of salt, pinch of cayenne pepper, six cloves, chop one carrot, one onion and five stalks of celery fine. Add this to the stock; put in the tongue and simmer until tender. When done take out and add to the gravy one tablespoonful each of made mustard, catsup, mushrooms and Worcestershire sauce, one cup port wine, two tablespoonfuls butter, mixed with three tablespoonfuls brown flour. Boil and stir until smooth. Put back the tongue and simmer ten minutes. Then place on a platter, pour the gravy over it and garnish with slices of lemons and celery leaves.



A Bright Light For a Dark Night

Every man who has use for a lantern should go to the nearest dealer and examine the Liberty Lantern. If only for their convenience it would pay you to replace your old ones with

Liberty Lanterns

Hay.

Scott & Magner say under date of March 27: The recent storm which we have had in general throughout the state has been particularly beneficial to the southern portion, and came at a time when it could well be used, and was needed. A general report however, from different sections of the interior shows that the season is somewhat late, and it is the general impression here among dealers who are thoroughly posted on the situation, that we have only about enough hay to carry us through, and that prices should be maintained strongly right up to the time when new hay begins to arrive. The immense acreage, however, that is sown to hay this year and the apparent large yield that we are going to have, will change the situation immediately after the first cars of new Hay begin to come in.

Reports from the interior are to the effect that trading has been quiet, being interrupted by the bad weather. This has undoubtedly had somewhat of an effect upon our daily receipts. Export trade has been quiet, but steady, and daily general business has continued with the demand strong and regular.

Alfalfa is weakening, and will probably continue to go off now from day to day, as the green feed begins to take its place. Only the limited supply keeps the price where it is, as any quantity coming in here would immediately cause quite a slump in the alfalfa market.

Citrus Market

LOS ANGELES, March 31, 1909.

About 130 to 140 cars of oranges are going forward daily at this time. The market condition is much better than it has been for the past three weeks. In fact the prices prevailing at the end of February have again been resumed and even better. From present indications a still better condition will prevail and all navels from this time on will command quick purchasers. This condition is not confined to any one section but is general in all Middle West and Eastern points.

Lemons are also improving in market tone and better prices for several weeks now prevail. This is probably only the forerunner of still better conditions as the summer approaches. Foreigns are coming in liberally but do not seem to effect the prices for Californias.

Shipments.

Total shipments to date since November 1st, aggregate 14,436 cars of which 17,247 were oranges, 2,181 were lemons. To this same date last season the shipments were 19,428 cars of which 17,247 were oranges, 2,181 were lemons.

Cream Separators, all sizes, all prices. O. J. Weber Co., 225-227-229-231 East Sixth street, Los Angeles.

NEW YORK, March 29.—Forty-eight cars oranges and two cars lemons sold. Market is very strong and higher on oranges. Weather clear and favorable.

THE PROBLEM OF SUMMER COOKING.

The weather man says it's going to be a hot summer. This is setting good housewives thinking about the kitchen work—wondering if last summer's toil and worry over a hot stove in a hot kitchen must be all gone through again—wondering if there isn't some way of roasting, toasting, broiling, frying, ironing and washing without having the kitchen like a boiler room.

There is. No longer need the approach of summer be viewed with dread by the woman who keeps house, for science has made is possible for her not only to do all her stove work quicker and better than ever before, but to do it without the kitchen temperature being intensified to any noticeable degree provided she uses a New Perfection Wick Blue Flame Oil Cook-Stove.

The "why" of it is to be found in the wonderful burners of the "New Perfection," which produce intensely hot blue flames, and yet so concentrate the heat that it is not thrown off into the room to cause discomfort. In this way the housewife is enabled to do her kitchen work in comfort—to say nothing of the time saved in lighting—of having no hot fire when the stove is not needed—of being able to get a flame of any required size at will, from one for simmering to one for quick boiling or any other purpose. In fact, while one flame is working away at full blast, the other two can be at medium and low heat—something that cannot be done with a coal or wood stove.

When washing day comes around there is no need for carrying in coal or wood—nor is there any waiting for the fire to get started. The same holds true on ironing day and baking day. All this, added to the splendid results, makes the "New Perfection" an unusually convenient stove to have in the house.

Then there is the cabinet top, which gives the "New Perfection" the appearance of a modern steel range. Its commodious top shelf is extremely useful for warming plates and keeping cooked food hot. Also has two drop shelves on which to stand the teapot and coffee pot. In fact, the "New Perfection" has every convenience—even to bars for towels.

"The "New Perfection" burns ordinary kerosene and effects no small saving in fuel expense in the course of a single season.

Another member of the "New Perfection" family is the Rayo Lamp—an all round house lamp in which illumination by means of kerosene approaches more nearly perfection than in many expensive and complicated systems of lighting. Its latest type of central draft burner and its beautiful porcelain shade unite in producing a light of great brilliancy—yet so mellow as not to tire the eyes.

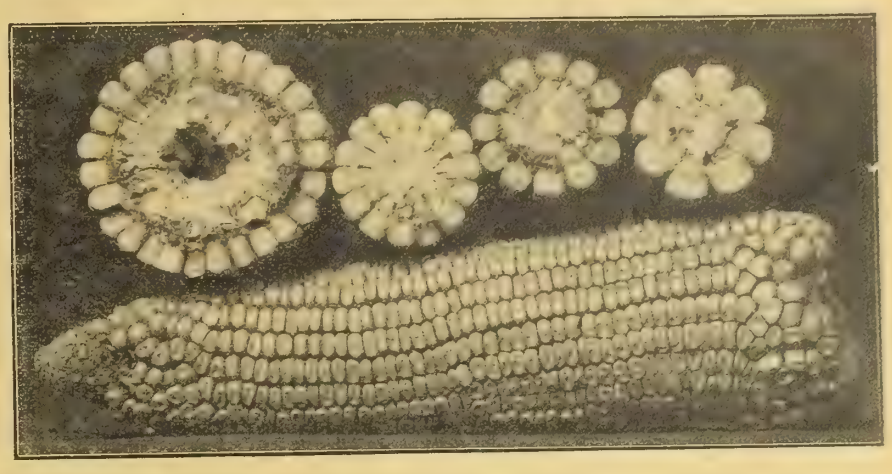
Whether used in library, parlor, bedroom or dining-room the Rayo Lamp is never out of place, as it harmonizes with the furnishings of any well kept room.

The New Perfection Wick Blue Flame Oil Cook-Stove and the Rayo Lamp, combining as they do beauty, convenience and low price, should be in every home where real comfort is a consideration.

The Seed House of the Great Southwest

CORN CORN CORN

1 2 3 4



1 El Monte Monster. 2 Orange Co. Prolific. 3 Pride of North. 4 Hickory King.

The above cut shows a full ear and a cross section of the El Monte Monster, a large-eared, white dent corn, as compared with the Hickory King, Orange County Prolific, and the Pride of the North. Twenty-six and twenty-eight rows is not unusual.

Mr. Thos. Herbert, El Monte, says if he would have had a good stand, he would have averaged nearly 100 bushels to the acre. All of his neighbors have purchased of this variety for next season. Matures in one hundred days.

Price, per 10 lbs. $1.00; 100 lbs., $7.50.

Orange County Prolific

A Medium Sized, White Dent Corn

Our attention was called to this wonderful, remarkable corn by Mr. McLaren of Santa Ana, who says his crop averaged 110 bushels per acre. Many stalks matured fine, full-sized ears, while few had less than three. Like the El Monte Monster, McLaren's neighbors have already bought much of our supply. As an ensilage corn there can be none better because of the profuse foliage and numerous ears. Matures in one hundred days.

Price 10 lbs. $1.00; 100 lbs. $7.50.

Hickory King

We have secured an exceptionally pure strain of this variety. It is too well known to need description, but we call attention to the large, white dent grains and the very small cob. Mr. Chas. Fawcett, El Monte, says he has the best success with this variety, as it yields nearly twice as much on his land as the yellow dent varieties. It is a late variety, requiring one hundred ten days to mature. It is a rank grower and an all-round favorite.

Price 10 lbs. 50 cents; 100 lbs. $3.50.

Pride of the North

A ninety day yellow dent, has long been a favorite in Southern California. Mr. Thurman of El Monte planted twenty acres about the middle of last July, and harvested more than one thousand bushels of corn. For late planting on damp land, or for early planting on dry land, this variety should always be selected. It never disappoints, but always surprises.

Price 10 lbs. 50 cents; 100 lbs. $3.50.

OTHER VARIETIES OF CORN mentioned below are too well known here to need detailed description; they have long been the leading sorts, and we always carry a large stock on hand for each season's demand.

Early Mastedon.—Having grown and sold the Early Mastedon corn four years, we recommend it as being decidedly the best of all yellow Dent varieties. Everyone who has seen it grow is enthusiastic in its praise. Large ears, deep grains, and as many as 24 rows on a cob. **Eastern grown, per 100 lbs. $3.50.**

The Iowa Silver Mine.—A large White Dent. The grains are as large as the Hickory King, but longer, having a small cob. It is the most desirable of all White Dent varieties. **Per 100 lbs. $3.50.**

Red Cob, Ensilage.—A large stalk with a profusion of leaves which makes it the most desirable for ensilage. **Price, per 100 lbs. $3.50.**

Reid's Yellow Dent.—This is the variety that has been brought to a high state of perfection by the Illinois growers, and drew the medal at St. Louis because it averaged the greater number of pounds per bushel. **Price per 100 lbs. $3.50.**

King Phillip—90 days. A small, yellow variety of Flint corn; very popular in this market. Price on application.

Oregon Evergreen Sweet Corn

Oregon Evergreen corn now has the endorsement of every gardener that grows for the Los Angeles market. We are safe to say that any gardener growing this corn for any other market, will have the lead of all competitors just as soon as he will show to his customers its superiority over all other sweet corn.

This is the fifth year since we first offered this new and distinct variety. The demand has grown each year until it is now practically the only variety offered on the Los Angeles market. The peddlers will have no other and one no longer hears the consumer complain about the poor quality of the California sweet corn. The advantages of this corn over all others, is its earliness, its large size, rarely less than eight inches long clear of husk. The grains are full to the tip. The husk is very thick and folds tightly over the grains that the worm does very little damage compared with other varieties. The thick husk is also desired by the peddler and the grocery man, because it can be held over two days before it appears old and wilted. It is very productive, averaging three good ears to every stalk; often bearing five marketable ears.

It can truthfully be said that Oregon Evergreen has excluded every other variety of sweet corn from our local market. **Price, ¼ lb. 5 cents; ½ lb. 10 cents.; lb. 15 cents.** By mail add 10 cents per lb. extra. **100 lbs. $8.00.**

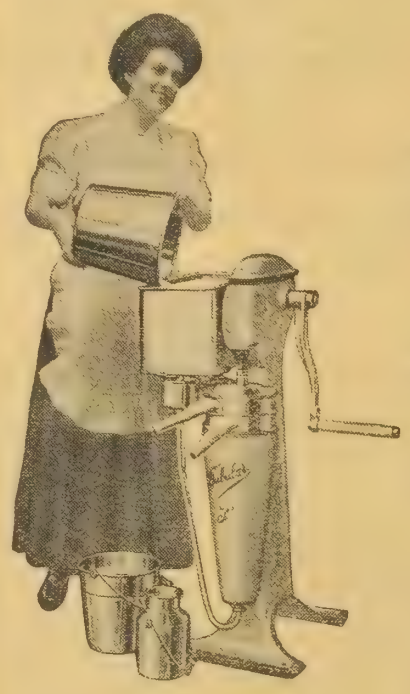
How The Farmers Voted

TRADE Sharples MARK 29 Yrs

We recently offered a beautiful calendar to **every** farmer sending us his name and address and telling us how many cows he had and **what make of cream separator he owned.** We received many thousand replies. **Every one of these farmers told us the name of the separator.** It was just as though the farmers had **voted** to decide which cream separator is best.



Tubular supply cans are low, steady, and need not be removed to take the machine apart. A plumb bob is attached to the back of our 1909 Tubular "A" for quickly leveling the machine.

Almost Half Say Tubular

More than 41 per cent.---**almost one half**--of all the separators owned by these many thousand farmers are Tubular separators. There are **more than twice as many Tubulars** as the three leading "bucket bowl" separators **combined.** This absolutely proves that **farmers like Sharples Tubulars best.**

This is the farmers' verdict. Farmers are so thoroughly convinced that Tubulars are way ahead of the very best "bucket bowl" machines that they have bought over twice as many Tubulars as they have of the three leading "bucket bowl" separators combined.

You will make no mistake in buying a Tubular. Made in the world's greatest separator factory. 1908 sales way ahead of 1907--out of sight of most, if not all, competitors combined. The additional fine features of our 1909 Tubular "A" are making 1909 better yet. Write for catalog No. 260.

Sharples Tubular Cream Separators run so easily that the medium sizes can be turned by one who is seated.

WILLIAMS' GOOSE-NECK CULTIVATOR

Patent applied for
ARNOTT & CO., General Distributers,
112 So. Los Angeles St., Los Angeles, Cal.

Especially adapted for citrus orchards. Sizes 7 to 14 ft. Lightest draft. Write today

The following is a sample of the unsolicited testimonials received regarding the Williams Goose-Neck Cultivator:

Merle, San Diego County, Cal., March 25, 1909.

Arnott & Company,
Los Angeles, California.

Dear Sirs:—You may recall that I recently purchased one of your Williams Goose-Neck Cultivators. I wish to say that I am exceedingly well pleased with it. In fact, as I told Mr. Jones, your representative in Oceanside, I would not take $500.00 for it if I could not get another. This is not an exaggerated statement, I mean it literally. In this section we do not have irrigation and everything depends on proper cultivation, so that good tools are very important. There are three points in which the Williams Goose-Neck Cultivator surpasses all other cultivators which I have seen, viz:

First. The draft is very light. My two horses weigh 900 lbs. each and they have no difficulty in drawing the 7 ft. cultivator.

Second. The Williams Goose-Neck Cultivator stirs the soil well without exposing the subsurface, thus preventing the escape of moisture.

Third. The cultivator being of low construction, one can cultivate under the trees as easily as harrow.

I was showing my cultivator to a neighbor the other day and had him take it home to try it. The use of it for half an hour so thoroughly convinced him of the merits of the tool that he has, through Mr. Jones of Oceanside, given you an order for one-half dozen cultivators.

Messrs. Williams & Son of Orange certainly deserve great credit for inventing the Goose-Neck Cultivator.

Sincerely yours

LOUIS C. LUHR.

WILLIAMS & SON, Mfrs., Orange, California

California Cultivator

Vol. XXXII—No. 14 Los Angeles, California, Thursday, April 8, 1909 Subscription $1 a Year

Some Products of the Hawaiian Islands

Written for the Cultivator by W. B. Thomas of Wahiawa, near Honolulu. Mr. Thomas is now a Pineapple Grower, but Will be Remembered by Many as a Former Owner of the Cultivator

AS IS pretty generally known everywhere, the production of cane sugar is the principal industry of the Hawaiian Islands—indeed, the value of the sugar crop is about eight times that of all others combined. Instead of thousands of small farms, owned by individuals, this sugar is grown on vast estates of thousands of acres, each owned by corporations with a capital of from one to five million dollars.

Plenty of Fertilizer.

Intensive culture is the rule and every means known that will increase the output in field or mill is used. Fertilizers are liberally applied—from $40 to $50 an acre per crop. Eighteen months from time of planting is required to mature the first crop. One year later a second crop is harvested from same planting. Then mammoth steam plows turn over the land to a depth of 24 to 30 inches and the field is replanted. The same goes on year after year. No rotation of crops and no rest for the soil. In spite of this heavy drain, the annual yield per acre does not seem to decrease. Some of the most productive plantations produce an average of ten tons of sugar per acrde and occasionally thirteen tons have been produced on an acre. To do this, over 100 tons of cane must be grown. I am sure it would be hard to convince some farmers in the states that one hundred tons of anything could be grown on an acre of land in one crop, but it has been done here frequently. Even with the application of a ton or more of fertilizer per acre a year, it is surprising how the land will continue to do this year after year without rest or change of crop.

Irrigation.

Immense quantities of water has to be used. During the greater part of the year the crop is irrigated every ten days. Most of the water supply comes from artesian wells at or near sea level and as the land rises from the sea to the mountains, huge pumps are required to lift it. In some instances as high as 700 feet, but 450 feet is as high as it is generally considered profitable to pump water. Single plantations pump from 40 to 50 million gallons per day—as much water as the city of San Francisco uses.

Labor.

From two to three thousand laborers are employed on a plantation. Wages are from $18 to $23 per month, with free house, fuel and physician's services. There is no necessity for them to lose any time either. They can work every working day in the year. Thus it will be seen a laborer can average as much per year as he could in the states where the pay per day is higher.

Before the islands became a part of the United States, the labor question was easy, as there were no restrictions on emigrants coming from any country. Chinese came in large numbers and they made splendid workers. Several thousand Portugues also came and they too proved good workers, thrifty and law-abiding. After annexation, when Chinese were no longer admitted, the planters turned to Japan and thousands of men and women from there were brought in to work the rapidly growing plantations. Within the past two years, however, that source of supply has been cut off and the world is being searched for people to carry on the work.

Over $300,000 was spent by the sugar planters in the past two years in bringing about 5000 Spaniards, men, women and children, from their homes across the seas. All their expenses were paid by the planters from the time they left their homes till they reached Honolulu. After they arrived here they were free to go where they pleased, but most all of them took the work offered them on the plantations, and are satisfied and doing well. On some plantations each family is given an acre or more of ground on which to grow vegetables, etc., and make a home.

Following their custom of returning to China as soon as they accumulate some money, or as they grow old, the Chinese have been leaving the islands or drifting into other lines of work, until now there are not many left on the sugar fields and thousands of Japanese went to the Coast States before the law preventing them was passed. The result is the sugar growers see a serious shortage of help in the near future unless something is done soon to induce others to come.

To raise the necessary funds to do this, a number of prominent planters appeared before the Territorial Legislature this month and asked it to pass a law levying a tax of two per cent on all individual incomes of $4000 or over. It is claimed

A Scene on Mr. Thomas' Plantation.

about $400,000 could thus be realized, and of this about three-fourths is to be used for immigration purposes and to balance expended in conserving the forests and water supply of the islands. It is proposed if possible to bring Europeans who will in time affiliate and become citizens, and thus help carry out the purposes of the National Government in Americanizing the islands.

Although this tax will have to be paid only by the rich, there is considerable opposition to it by some of the native members of the Legislature and a few cheap politicians who try to curry favor with the native vote. The natives say they are afraid if large numbers of possible citizens are brought in they will eventually rob them of their control of the islands at the polls.

Conservation.

To show the importance of something being promptly done towards conserving the forests and water of the islands, Mr. E. D. Tenny, a prominent planter, addressed the Special Legislature Committee and gave some figures on the artesian water consumption of the island of Oahu that I think would be interesting to the readers of the Cultivator.

Mr. Tenny first gave the area of the Island, the area of the cane plantations, and the water drawn, with water terms, Mr. Tenny showed

Island of Oahu Area is 600 square miles or	384,000	acres
Area of Cane Plantation about	37,500	acres
Daily Pumping Capacity of Plantations	351,250,000	gals.
Daily Pumping Capacity of Honolulu Water Works	11,250,000	gals.
Hawaiian Electric, Rapid transit, Hon. Brewing & Malting Co., Young Hotel, Hon. Iron Works Co., Oahu Ry. & Land Co., Pacific Fertilizer & Guano Works	4,000,000	gals.
Rice Plantations and Dairies, Individuals, Etc.	50,000,000	gals.
Total Daily Draft on Artesian System	416,500,000	gals.
Total Yearly Draft on Artesian System	152,022,500,000	gals.
or say, in round numbers	150.000,000,000	gals.
or	20,000,000,000	cu. ft.
or	429,137	acres

After presenting the situation in tabular form Mr. Tenny drew attention to the fact that outside the plantation wells and the Honolulu Waterworks the figures could not be absolutely accurate, as the exact number of wells supplying rice plantations and private places was not exactly known. These had to be estimated, but the figures given were considered very conservative.

Putting the figures in a popular form, as a million gallons does not mean much to the citizen not familiar with water terms, Mr. Tenny showed that the amount of water used from the artesian system alone on this island was equivalent to 1.2 feet or 14½ inches depth of water distributed over the entire area of this island.

To deliver the 416,500,000 gallons used daily would require a ditch 40 feet wide and 5 feet deep, flowing at a speed of 180 feet per minute.

The yearly supply would fill a lake three miles wide and 20 miles long and 10 feet deep.

The rainfall in Honolulu for the past 24 years, from 1885 to 1908 inclusive, averaged 29.28 inches.

Cotton.

The Hawaii Agricultural Experiment Station for a couple of years has been experimenting with different varieties of cotton, and from results obtained it gives promise of taking a prominent place in the islands' industries. The Sea Island and Caravouica "Wool" types give the greatest promise. The former is said to supply the highest quality of lint in the world, and brings twenty cents and upwards a pound.

With the Citrus Growers

THE REAL MENACE OF WHITEFLY

FROM the Jacksonville Times-Union we take the following which gives an insight into the true situation as to Whitefly:

It has been calculated by Prof. P. H. Rolfs that the whitefly population in mid-summer, of a fully infested umbrella tree of medium size, bearing about 20,000 leaves, may be 20,000,000 larvae. Dr. A. W. Morrill, basing his calculations upon a tree of similar size, gives an estimate of about 11,000,000. Both of these investigators, in order to be well on the conservative side, accepted the lowest figures of their calculations; whereas the average number of insects per leaf, according to their actual counts; would have given something like 70,000,000 to 80,000,000 as the number of larvae per tree. From this last estimate, it is evident that a large umbrella tree may harbor 100,000,000 or whitefly larvae at one time. Allowing a dozen large umbrella trees to a town, we may have upwards of 1,200,000,000 adult whiteflies coming out of these trees during the latter part of summer.

What Becomes of Whiteflies.

Careful observations have shown

A Great Aid to Fumigation

It is impossible to estimate the great benefit which the hydrocyanic-acid gas treatment has been to the fruit and especially the citrus industry of California. While it is not probable that the class of people engaged in the fruit industry here would have allowed their trees to have been destroyed by scale pests had not this treatment been discovered, it would yet have been far more difficult than it is with this effective remedy at hand. Spraying had the preference with many growers of Southern California for many years principally because of its greater economy and while it is yet much cheaper than the fumigation treatment, the latter has been so perfected and the methods of its application so much more thoroughly understood and applied that it is today by all means the best remedy for eradicating insect pests.

One of the most serious hindrances to its success in the earlier periods of its use was the unequal character of the cyanide used. It was soon determined that some applications burned the trees far worse than others. Methods of correcting this evil were studied by many, and many experiments failed. Different proportions of acid and water were tried all of which tended to perfect the system. Along another line chemists took up the study of the action of the acid of cyanide and also the quality of the chemicals.

Amongst those who have been of greatest assistance in developing along the lines of the chemical betterment, we may mention Mr. F. W. Braun, Los Angeles. Mr. Braun began studying this question as far back as '88. He soon succeeded in learning many of the mistakes which were being made by fumigators and for the past ten or eleven years the chemicals practically as used now have been at the command of the citrus growers, and largely because of Mr. Braun's investigations. Mr. Braun has been a persistent and a consistent believer in fumigation.

F. W. Braun, Los Angeles.

If this paper were contemplating a series of articles regarding men who have done things in a large way for the benefit of the citrus industry, the subject of our first article might well be of Mr. F. W. Braun.

Mr. Braun is now putting out an instructive circular on fumigation which he will be glad to mail on request. Write F. W. Braun, Los Angeles.

that these swarming millions of winged whiteflies deposit only a comparatively small number of eggs upon the leaves of the Chinaberry and umbrella trees at this time, but quit these trees and deposit eggs upon evergreen food-plants, principally citrus, privet and cape jasmine. Whether they do this instinctively, because the Chinaberry trees lose their leaves in the fall and winter, so that the larvae from any eggs laid on their leaves must die, or whether the leaves of these trees have developed some repellant quality; or whether the quitting of these trees is caused by overpopulation; does not affect the result. The fact is that these whiteflies swarm about and either fly or are driven by the wind for long distances many of them finding at last suitable plants on which to deposit their eggs.

Last summer the small citrus trees at the experiment station were free from whitefly; but in August and September thousands of whiteflies were hovering about and depositing eggs, so that by the end of fall these citrus trees were as heavily infested as citrus trees commonly become. The nearest infested trees from which the whiteflies could have come were umbrella trees in Gainesville about a mile away, so that the whiteflies had to travel at least a mile. That many whiteflies must have gone farther out into the country than the experiment station, can hardly be doubted considering the great numbers in which they were swarming about, not only on citrus trees, but on other plants, on clothing, windows and vehicles. The principal food plants in Gainesville and North Florida are Chinaberry and umbrella trees, there being only enough citrus, privet and other evergreen food plants to bring about the restocking of the deciduous trees every spring.

What Is To Be Done.

That hundreds of millions of winged whiteflies may become matured on Chinaberry and umbrella trees, and that these hordes of insects may swarm for the distance of at least a mile, and perhaps several miles, from their place of breeding is an established fact. Therefore these trees should be destroyed before next spring, and before they become infested again by the spring brood of whiteflies. They should be destroyed for three reasons.

1. Because these trees reduce the efficiency of all measures for the control of the whitefly by one-half or more, or perhaps nearly nullify them, by setting free swarms of whiteflies into the citrus trees at a time when the fruit is maturing and it is most desirable to have the trees free from whitefly.

2. Because in newly infested localities these trees are hastening the dissemination of the whitefly into the non-infested groves. Besides the spreading of the whiteflies from them through the air, teams are hitched under such trees and the vehicles become agents in carrying to other Chinaberry and umbrella trees, but which the team might again be hitched.

3. Because of the nuisance to man and beast from the myriads of whiteflies which frequently fill the air in whitefly infested sections. That this nuisance is principally due to the presence of Chinaberry and umbrella trees is evident from the fact that it occurs in sections where there are Chinaberry and umbrella trees, but where few or no orange trees are grown.

KEROSENE EMULSION.

From the slips handed out on the Demonstration Train to inquirers asking as to making kerosene emulsion, we quote the following directions as recommended by the State Horticultural Commissioner:

Coal oil (150° test)	4 gallons
Laundry soap	1 pound.
Water	2 gallons.

Dissolve the soap by boiling in the water, and when dissolved and while boiling pour with a dash into the kerosene. Churn the mixture for 10 or 15 minutes, either by pouring back and forth from one vessel to another, or by the use of the pump by pumping the liquid back upon itself. The emulsion should have the consistency of cream.

No. 1—For a winter wash when trees are dormant, use: One gallon of emulsion to six gallons of hot water.

No. 2—For a summer wash use: One gallon of emulsion to 10 gallons of hot water.

For black scale and peachtwigborer spray in December, January and February with No. 1.

For prune aphis, rose aphis and woolly aphis use No. 2.

All About the Orange and Lemon

Is told in our new book on Citrus Culture, embracing every phase of the subject from the seedling plant to the final disposition of the fruit in the Eastern market. The largest and best book on the subject ever printed—60,000 words, 100 illustrations. You will want a copy, which we will send you for the small sum of 25 cents. Remember we are the largest growers of orange and lemon trees in the world.

Deciduous Fruit Culture

By J. W. Mills

THIS YEAR'S APRICOT CROP.

THE Cultivator has begun to gather so far as possible at this date, the information in regard to the coming year's apricot crop. Various sections of the state have been written to and by another week we hope to have a liberal number of answers which will give a fairly good indication of the situation all over the state. From the number we have sent out a few given below have already been sent in. These are all from the southern end of the state excepting one from Mr. Coates at Morganhill. From these reports we would infer that the coming crop will be if not a bumper one, at least a good sized crop. With a fairly clear market it surely seems as if the returns should be good, and with the good crop promised must look good to every apricot grower in the state. From the replies so far received we quote:

G. H. Waters, Canner, Pomona, Los Angeles County.

There is a fine showing for apricots in Pomona valley, but the acreage is decreasing all the time. No new orchards are being planted to apricots, there will be 1000 tons of green fruit to market in Pomona valley this season unless something hapens to the crop very soon. Peaches are blooming very heavy.

J. A. Wilson, Secy. Chamber of Commerce, Santa Ana, Orange Co.

I have made enquiry as to the apricot crop of Orange county, and I find we will have a full crop, as the indications show today. Perhaps some orchards will have to be thinned, or the fruit will break the tree. Rain did not injure the crop at all.

Leonard Coates, Morganhill, Santa Clara County.

The apricot crop, except of Moorpark, promises fairly well about Morganhill, and it varies in the county from poor to good. It is too early to tell the effect on the crop of the present cold winds.

C. Thorpe, Cashier F. & M. Bank, Santa Paula.

Relative to the probable apricot output this coming season, will state that I believe we will have about 350 tons in the Santa Paula district and about 1300 to 1400 tons in the entire county. The trees are heavily loaded and the ground in fine shape and the fruit should be of fine quality and I believe will be good sized. The above estimate is for dried fruit.

CALIFORNIA RAISIN DAY.

The raisin men of California have decided on April 30th as "Raisin Day" and are organizing to make it a success. The co-operation and assistance of railroads, steamship lines, hotels, and mercantile establishments throughout California will be asked.

A meeting was held in Fresno on March 10th attended by representatives from over the Valley of the raisin interests and by representatives of the Southern Pacific Company.

At this meeting the Executive Committe of the Chamber of Commerce decided to raise $35,000 or more to tell in simple language just how much good it will do the average citizen to eat raisins and how to prepare them. This on Raisin Day, with the hope that hereafter they will help to dispose of the 25,000 tons of lucious fruit Fresno has on hand.

The campaign is not confined to California but is to be pressed vigorously throughout the East.

The Southern Pacific Company has agreed that all of its traffic forces shall work to make Raisin Day a success. In all of its stations, in all its suburban trains, in all its ferry boats, on all its Atlantic steamers, it will put up posters advertising Raisin Day.

On all Southern Pacific diners and in all eating stations raisins are to be served gratis on Raisin Day with compliments of the California Raisin Growers. The other Harriman Lines will co-operate and without doubt take similar action. The lecture bureau of the Harriman Lines in the East, under charge of Mr. J. W| Erwin, will have a series of lectures delivered on the use of California Raisins and the observance of Raisin Day, reaching probably 25,000 people.

The San Francisco hotels have already signified their intention of aiding, and will no doubt take concerted action.

A million raisin primers with recipes will be distributed over the United States, telling people how to serve raisins and instructing them in their uses. Every business man in California will receive a request to help observe Raisin Day by making his friends and patrons more familiar with one of California's choicest products. Altogether it is expected to discount Thanksgiving records on April 30th, and to make the people of the United States generally sit up and take notice of California Raisins.

Subsequently an advertising campaign will be undertaken to keep raisins to the front throughout the country.

RHUBARB ASSOCIATION.

The Southern California Rhubarb Grower's Association is making a persistent effort to market this product in a way so as to secure for its members compensation for their labor in growing this luscious product. The organization which was formed some weeks ago includes in its membership more than 95 per cent of the growers of the southern part of the state. The members are enthusiastic and it is believed that a successful basis of marketing will be reached by which fair returns may be had. A membership fee of only 50 cents is exacted from those who join and a sinking fund is to be made up of 2 per cent of the amount shipped by each member. The officers are S. D. Teel, Santa Ana, president; H. M. Bateman, Monrovia, vice-president; J. A. Holland, Santa Ana, Secretary. The directors for the remainder of this year are J. B. Wagner, Pasadena; C. R. Haines, Norwalk, A. L. Page, Chino. The year ends in September. The marketing will be largely in the hands of Mr. J. W. Beasley one of the large fruit and vegetable dealers of Los Angeles. The brand which has been adopted by the association announces in large type on the end of each box that the contents were packed by the Southern California Rhubarb Grower's Association and is "a product of Southern California, unequaled for sauce, pies, jellies, jams and fine confectionery." The association is worthy the ablest support of the rhubarb growers and will, we believe, lead to greater profits to the entire industry.

HAWAIIAN PRODUCTS.

(Continued from Page 403.)

The Caravouica, of which there are several types, was originated in Queensland, Australia, eight or ten years ago, and is said to be a cross between two strains of Sea Island cotton. Although the quality is not quite so good as the Sea Island, the percentage of lint to seed is much higher. Offers have been received here of from 16 to 23 cents per pound for all that could be supplied of this cotton. It is thought this crop can be profitably grown in the islands as a perennial. Individual cotton trees ten years old and over have been reported in different parts of the islands. A test picking of the Caravouica was made at the Station last August which gave a yield of over five pounds seed-cotton per plant. At that rate, figuring 625 plants to an acre, and 20 cents per pound, the value of crop would be $625 an acre.

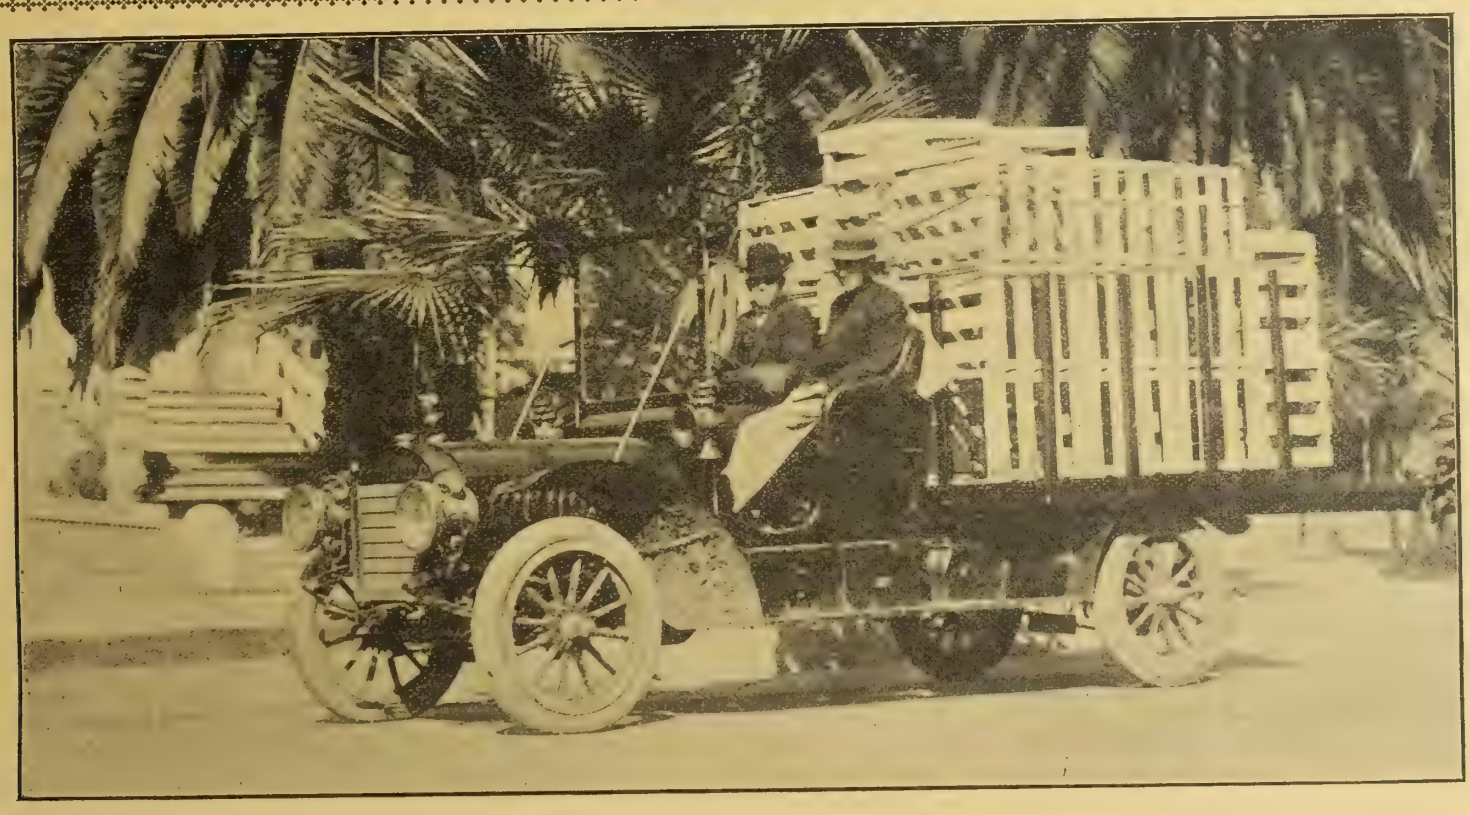
There are thousands of acres of land unfitted for any of the crops now grown that are admirably suited for cotton, and since a great many individual experiments are being made of from one to fifty acres, in a year it will be known just what can be done with it in the regular way.

The Luscious Pineapple.

Pineapples, a comparatively new crop, are firmly established now, and eight or ten thousand acres are devoted to them. Last year's output of canned pineapple amounted to 400,000 cases of two dozen each. The quality is as much superior to that grown in other countries as a Riverside or Redlands navel orange is to a coast seedling, and in order to let the public know it and to increase the consumption the Pineapple Growers' Association the first of this year started a systematic campaign of advertising in the leading magazines of the country. About $35,000 has been expended so far, with gratifying results, and it is intended to continue the work indefinitely. Each member of the association is assessed in proportion to the number of cases he packs.

Heretofore pineapple has been looked upon as a luxury by the majority of the people; to be eaten only on special occasions, but now this delicious fruit can be bought at prices no higher than is asked for the same grade of peaches, apricots and other fruits. There are nine canneries in the islands, all located on or near to the fields. The pines are left on the plant until fully ripened and canned the same day. Practically all the work in the canneries is done by machinery,—the paring coring, sizing and slicing,—and every employee handling the fruit wears rubber gloves, so that from the time the pines enter the cannery until they are in the cans they are untouched by human hands.—W. B. Thomas, Wahiawa, Hawaii, March 18, 1909.

Owners of 850 acres of orange trees at Riverside have combined to buy fumigating outfits.



RAMBLER AUTO TRUCK WITH LOAD OF GARDEN PRODUCE.

Along the San Fernando road, near Los Angeles, California, people who get up at daylight frequently see a large commercial vehicle rolling smoothly along with a ton of boxes and crates piled high up on the body. In these boxes and crates are celery, apples, beets, onions, potatoes, lettuce, cabbage and cauliflower.

This auto truck is a Rambler Chassis with a special interchangeable body built in Los Angeles.

J. Q. Adams, of Eagle Rock, has adopted this method of making his morning deliveries of garden produce in that section. This market gardener has been using three wagons to transport his merchandise, but found that in muddy weather there was a great loss of time on the road. The car is making good and carries three ordinary wagon loads of produce at a faster rate than a horse-drawn vehicle could make a single trip with one-third of the load.

The car has a forty horse power motor and is driven with side chains. The tonneau of the car has been removed, the frame lengthened fifteen inches, thus giving the car a wheel base of 127 inches. Solid tires have been placed on the rear wheels and the car has a capacity of a ton or more.

CONGO NEVER LEAK ROOFING FREE SAMPLE

A Genuine SURETY BOND GUARANTEE with every roll of Congo

So many guarantees are given nowadays that to a certain extent they have lost their value; but the one which accompanies each roll of Congo is different from all others.

It is a genuine Surety Bond backed by the National Surety Co., one of the largest and best known Surety Companies in this country. It protects you absolutely.

It is a distinct, clear-cut guarantee, and any man who desires the best roofing for his money, and wants the same backed by a reputable house as well as by a Surety Bond, can do no better than invest in Congo.

Samples will be sent for the asking, and we know if you test it thoroughly, as a roofing should be tested, there will be no hesitation on your part in securing it quickly.

Further information, samples, etc., on request.

Small Fruits and Vegetables

AS TO VEGETABLES.

THE list of vegetables generally used for table comprises nearly 100 varieties. Each of them is grown in some locality, grown and used with profit. Perhaps not one gardener in the United States grows them all, and very few grow as many as fifty sorts in the same season. There are a dozen leading products of the vegetable garden, which should be found in every farm cellar in the winter, yet as a rule very few carry over five or six in stock. And the number of families fully satisfied with two, the ever-present potato and cabbage, is legion.

The use of vegetables, as other foods, is largely a matter of habit. We get into ruts, and do not care to try new things. And yet all these different vegetables have a special value, if we fully understood it. Some of them answer the same purpose as drugs, only doing the work better, cheaper and more pleasantly. Spinach, kale, mustard and dandelion, are needed in the spring. They act on the kidneys, and purify the blood. Lettuce contains enough opium to be soporific. Onions and cabbage used in moderation cleanse the system, quiet the nerves and many times forestall the need of a physician.

Celery for the nerves has an established reputation. Asparagus and parsnips, cucumbers and radishes, beets and squash, green corn and beans, each in its season, supplies something for the physical system, some needed help which is not found so conveniently in any other form.

It is worth while to educate ourselves into the more frequent use of all of these aids to health. Health, individual and national, would be better, if we depended less upon the butcher, and more upon the gardener, for our table supplies.

We have good examples before us in Japan and Italy, which are practically vegetarian nations. Very little meat is consumed there by the masses of the people, yet they are strong, vigorous and healthy peoples. The art of properly cooking vegetables is not as yet fully mastered by many cooks, who are experts in other lines of cookery. The best practice is to put all vegetables on to cook in boiling water, and in uncovered kettles. If covered they cook too rapidly and the flavor is lost. Use salted water for fresh vegetables, except for those that grow underground. In the latter case salt is apt to harden them. Too fast cooking toughens the fiber and makes them tasteless. If vegetables change color it indicates improper cooking.

THE STRAWBERRY.

The strawberry has been under cultivation for centuries but systematic attempts at improvement are of comparatively recent date, extending back a little more than 200 years in Europe, and only about half a century in America. The earliest horticultural variety of which there is any account is the Fressant, which dates from 1660. Wild species of strawberry are few in number, certainly not more than a dozen, and only a part of these wild forms have ever been brought into cultivation. Nevertheless, so wide has been the variation under cultivation, that at the present time there is the anomaly of a fruit, appearing within a little more than a century, which the botanist does not refer to any species. Here then is a remarkable and practical example of experimental evolution. The history of this evolution has been fully worked out by Bailey, and a few brief notes of his investigations are given in this connection.

The systematic improvement of the strawberry began in England. The first foreign species to reach Europe was Frageria virginiana, the common field species of New England and the whole Atlantic coast. This is recorded in 1624, but does not appear to have varied greatly, and never found favor on the continent.—Green's Fruit Grower.

THE EVERGLADES.

The most successful growers of tomatoes and vegetables in Dade county have been those men who have farmed along the edge of the Everglades.

They are now experts in the culture and their opinion is the most valuable of any now available on the practical value of the draining of the Everglades, considered as a whole.

A careful investigation has been made among that class of growers, and they are almost a unit in opposing any general drainage plans.

They have come to believe that after years of observation and experiment, that they are protected by the waters on the Everglades and that the continual rise and fall of the waters, varying from times of drought to times of heavy rainfall, has a good effect on the soil, and that thereby their crops are enlarged.

Permanently removing the waters of the Everglades would destroy the vegetable raising of Dade county upon which the prosperity of this section has been built up.

The substitution of cane raising is a doubtful experiment at best, and its adoption would certainly destroy one great industry without replacing it with one whose success is positively assured.—Ex.

VEGETABLES IN THE KLONDIKE.

Dawson is to be credited with the discovery of the agricultural possibilities of the great valley of the Yukon.

A few seeds were first brought into the country by some of the "old-timers" who did not expect them to amount to anything.

They were planted on the sunny side of a cabin roof and they created a great deal of surprise and joy when they grew into an abundant supply of radishes and lettuce.

Today, hundreds of acres in the Klondike are being tilled and the vegetables grown are as fine as can be—equal to those that can be found anywhere in Canada.

The potato crop alone was over two hundred tons and the farmers and gardeners expect to double their potato acreage this year.

The territory of Arizona has appropriated $5,000 for the erection of a monument on the brink of the Grand Canyon in memory of John Wesley Powell of the U. S. Geological Survey. Mr. Powell was one of the first explorers to ever investigate the Grand Canyon of the Colorado.

Berry Plants

Buy direct from the farm. Strawberries, Black and Red Raspberries, Giant Himalaya Blackberry, Burbank's Phenomenal Berry, Mammoth Blackberry, Logan Berry and Dewberries; also Burbank's Crimson Winter Rhubarb.

Our catalogue is free and tells you how to grow berries of all kinds. Address

The Ornamental Garden

BULBS IN GLASSES.

Culture in glasses is no doubt the most interesting, and at the same time the least troublesome. Considering the price of really good bulbs it is a great wonder that they are not in every home. We periodically hear of many societies and charitably inclined individuals, giving out seeds free to children, to stimulate a love for plants, and when their plants have matured prizes are given to the most successful. We have not as yet heard of them distributing bulbs; and we offer the suggestion. It might be a trifle more expensive, but homes would be made brighter in winter; when even a green thing in a crowded tenement is a welcome sight.

The influence that this touch of nature exerts on the young mind is not at all, or only very little, considered or understood. The writer is placed in a better position than many others to study this.

The young mind is at its most receptive period, and is daily craving for excitement, or outlet for its animal spirit. Our reformatories, and truant schools are full of young boys and girls who have been deprived of some ennobling influence, whose animal natures have got the upper hand for lack of something that would interest and stimulate, in many cases, an abnormally active mind.

The proper channel has been withheld or denied, and the only channel left open—usually the street—has been the means of nearly every downfall.

From actual experience boys and girls that are incorrigible when kept at an indoor occupation, have become tractable, nay, even dispassionate, lovable and pliable when allowed to work among flowers and nature's surroundings; all of which goes to prove that the nearer you can keep to nature the less desire there is for the exercise of animal passions.

But we are digressing; this is a cultural article.

For culture in glasses the most suitable subjects are single "Hyacinths," "Chinese Sacred Lily," and "Polyanthus Narcissus."

Suitable glasses must be procured. They have a bowl-shaped cavity at the top, and the neck below this is contracted to keep the bulbs out of the water. Many object to this formal style of glass, and others cannot afford to buy them for this exclusive purpose. Any to whom these objections apply can use instead an ordinary bowl, and if expense be not the obstacle, any kind of a glass, or crystal dish such as is used for dessert, will also be suitable.

First fill up such a dish with (preferably white(stones—marble chips. If such cannot be got conveniently, any other kind of stone or pebble will answer the purpose, and also a few pieces of charcoal to keep the water sweet.

Fill up with water almost to the top, then set in your bulbs. It will depend upon the size of your dish how many bulbs it will hold. If it measures 6 inches across at the top it will hold 4 bulbs; if 8 inches, it will hold 8 or 10, and so on. Have the bottom of the bulbs as close to the water as possible without touching it, and put a few more stones around them to keep them in position.

Put them away in a dark, cool place until they have made six or eight inches of root growth, then bring them out in the room and stand them near the window. As the water gets used up, keep adding more, and also some fresh pieces of charcoal to keep the water pure.

When the dish is full of roots and the flower spikes are pushing ahead, one or two drops of household ammonia may be given about twice a week. This will help the flowers considerably.

By having several dishes in use, and starting them one at a time, with an interval of one or two weeks between, a continuous lot of flowers can be had all winter. Start with the early varieties first. Your bulb merchant will tell you which they are, or you can find out for yourself in the catalogue.—Gardening.

THE SURROUNDINGS OF OUR HOMES.

In traveling through a farming country one usually sizes up the occupants of a farm house by the neatness, or lack of it, evidenced by the surroundings. A little old house, with neat fence, clean yard, a few trees and a nice green lawn may look far more homelike than a large imposing looking house with confusion reigning around. The ash pile need not be near the door, nor an old stack of broken machinery near the front gate, nor need the hitching post be too close to the house. Trees grow so rapidly under irrigation that every one can have a few. To my mind they are indespensible to the home.

Next thing after trees, or perhaps before them, is a grass plot around the house. Blue grass and white clover seem to be the best combination here. The grass is the nicer alone, but the clover more hardy, and more easily and quickly started. Then let us have a few clumps of shrubs and flowers scattered around through it. Dahlias do very well, asters also. Cosmos make a showy clump for late summer and fall, but is a little too easily grown, and I fear may spread more than we like if we do not watch it carefully. When a climbing rose will grow vines eight or nine feet long the first year one need not lack for shade over windows and porch. The ramblers are so easily propagated by layering them. And a few grape vines cover a walk to the well or cave so nicely and give fruit the next year after planting.

LICE ON ROSES.

The lice on your rose plants can be gotten rid of. Dip the bush in water slightly warmer than the hand will bear, repeating the treatment several times at intervals of a day or two.

Dusting thoroughly with tobacco powder will also be effectual.

The white and green lice which attack the tender rose plants early in the spring may be destroyed by hot suds from the Monday's wash. Dash it on from different angles, as hot as can be handled, and the pests will disappear.

Such an application once a week will keep the foliage clean and promote the growth and health of the plants.

On extensive grounds where the grouping of shrubbery becomes an important factor in the architecture of the place, curved walks and circular drives are most pleasing and effective.

Legal Queries

Edw. L. Payne, attorney, 301-304 Douglas Building, Los Angeles, will answer legal queries in this department.

Immediate mail replies cannot be given except where fee to Mr. Payne is paid. When replies are wished in Cultivator address query to 115½ N. Broadway, Los Angeles.

Chattel Mortgage.

Will your query department please inform me as to whether a chattel mortgage holds after its maturity, and if so how long? The mortgage in question matured more than a year ago, but almost monthly or at least occasionally there has been paid various amount on the note. Does this renew it and is it perfecly safe to allow such a matter to rest without having a new mortgage made and recorded?—M. B., Los Angeles.

A chattel mortgage executed within this state holds for four years after maturity. Payments, monthly or otherwise, do not renew a promissory note. It is safe, so far as your right to enforce payment is concerned, to let the note and mortgage stand without renewal.—E. L. P.

Telephone Poles.

What can a property owner do to get two telephone poles removed from his property; they are about 30 feet inside the propery line, are there for several years (less than five). The Home Telephone Company and the Sunset Telephone Company say they do not think they own the poles and give no satisfaction to an order given to them to remove the offending poles. Can the property owner cut them down or dig them out, or burn them?—J. H.

Inasmuch as the poles constitute a private nuisance, the owner of the property upon which they stand has a right to remove them without unnecessary damage or to bring an action for ejectment. He should not burn them or cut them as that would be inflicting unnecessary injury on the company.

Waste Irrigating Water.

Can a railroad company or other property owner prevent me from running waste irrigation water from my land on the right-of-way, or other land, when there is no other place for the water to run? Before this railroad was built this irrigation water was run on and across what is now the right-of-way, and said railroad failed to provide an outlet through right-of-way for this waste. It has been more than five years since the road was built, and during all that time waste water has been running on the right-of-way and no legal steps have been taken to prevent it.—A subscriber.

Generally speaking, you have no right to turn waste water onto another's land to his damage.

If the water has been running uninterruptedly and without objection on the part of the railroad company for five years, and you have during that time claimed the right to have it run on the company's land, you now have acquired the right to run the water as heretofore.—E. L. P.

In addition to the attorney's answer, we may add that usually water is too valuable to waste on another's land. There are methods of irrigation by which such water and the fertility it carries off may be saved. —Ed.

Right of Way for Ditch.

I am pleased to see a space given for legal questions in the Cultivator. According to a recent paper, B would have a right of way after five years' use for water ditch. Can B get a statement in writing to that effect from A for right of way? Can B make A fence said right of way from stock? Suppose there should be a mistake in surveying and the ditch moved to correspond with the new survey (supposed to be on the line between two pieces of A)? Should B get a right of way from A for the new ditch before the old ditch was given up? Where can I get laws governing water rights of California?—A Subscriber, El Centro.

B can only get such writing as A is willing to give.

Generally speaking, it is B's duty to maintain his right of way, and he may go upon A's land for the purpose of keeping it in repair. A has no right to damage B's way; but A cannot be required to fence from stock if the stock only damage the ditch in the course of using the land in the ordinary methods, as for pasturage. And if the injury is negligently caused, your action would be for damages; you could not compell A to fence.

B should, by all means, get A's consent to move the ditch, as one has no right to change the location of a ditch on another's land after it has been once located by user of grant. I know of no compilation of the water laws of California. They are scattered through the codes and court reports. Well's Water Rights in Western States might be interesting and instructive.—E. L. P.

Railroad Right-of-way.

Has a railroad which has been in existence for over forty years, and with a right-of-way two hundred feet wide, any right to condemn land in order to lighten grades and shorten the distance, on the plea of wanting a double track?—Subscriber, Auburn.

The length of time the road has existed is not material, but perhaps the fact that its right-of-way is 200 feet wide would indicate that there is no necessity for more land in order to lay a double track. The right to condemn private property can be exercised when necessary, and at any time the railroad company can show that the location of the road can be improved. The question, as to whether the exigencies of the public can be adequately met and provided for in any other way, than by condemnation of the particular property sought, is generally determined in favor of the railroad, as it is regarded as a quasi public corporation.—E. L. Payne.

Executor Selling Property.

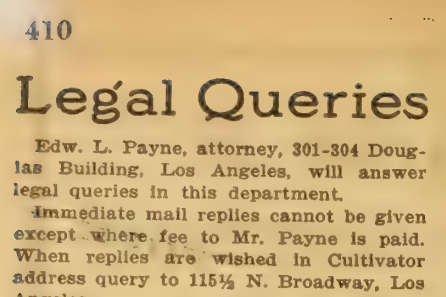
I will my real and personal property to my wife and children to share equally and I make my son executor without bonds, does the law permit him to dispose of property before my youngest child becomes of age?—J. J., San Diego.

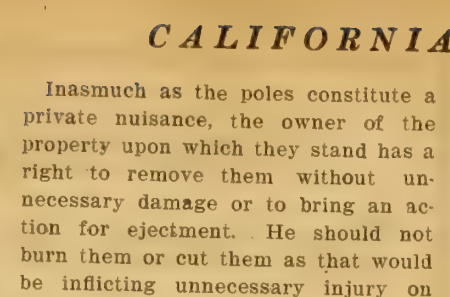
The executor may, with the consent of the probate court, sell property at any time before the estate is distributed if necessary to pay debts of the estate or decedent, expenses of administration, or if for the best interests of the state.

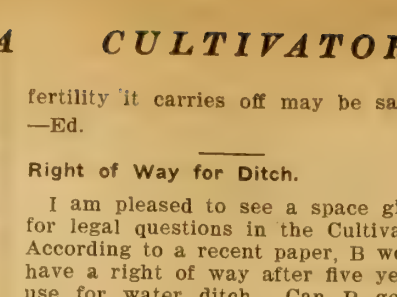
Excess Land.

I bought the north half of a 40 acre tract on Contract. The seller thinking he was selling me 20 acres. It turns out that the 40 acres over runs. Do I have to pay for the excess.—A. J. B.

If both vendor and purchaser thought that only 20 acres was being sold and by mistake the description included more, the purchaser has no right to the excess; but if the description calls for the North half of a certain lot of land and there are no words limiting the amount conveyed and both parties intended the deed should convey a half, whatever that might be, the purchaser then retains all conveyed. Again, if the purchaser knew that the deed called for more land than the vendee intended to convey and permitted him to make the deed thinking it called for less, the purchaser has no right to the excess without paying for it.—E. L. Payne.







Implements for the Ranch

We can supply **everything** that is needed in ranch implements. You can't afford to buy without first getting our prices and inspecting our goods. ROOFING GUARANTEES.

When a maker guarantees his roofing, it merely mean that he puts his claims for it in writing, and if there is any dispute afterwards, there are thousands of way in which the maker can evade responsibility if he chooses.

The makers of Congo Roofing, however, have devised an interesting plan which gives the buyer absolute protection. With each roll of roofing is furnished a Surety Bond issued by the National Surety Company of New York, guaranteeing the faithful performance of the guarantee by the manufacturers. This gives to any possible complainant a Court of Appeals to which he can go, over the head of the manufacturer. In fact, this guarantee bond so pledges that if the manufacturers of Congo Roofing should go bankrupt or close out their business, the Surety Company would still continue to guarantee the reliability and satisfaction of Congo Roofing. The guarantee on the three ply is for 10 years.

A copy of the Guarantee can be obtained by addressing the United Roofing and Manufacturing Company, Philadelphia, or Blake, Moffitt & Towne Los Angeles, Cal.

Live Stock and Dairy

Dairymen and stockmen are requested to write of their experience. Mrs. Sherman is always willing to answer queries and this, with experience of other workers, will make this department of greater value.

By Mrs. Minna E. Sherman

ANTHRAX IN CATTLE.

ANTHRAX, or charbon, may be defined as an infection disease which is caused by specific bacteria, known as anthrax bacilli, and which is more or less restricted by conditions of soil and moisture to definite geographical localities. While it is chiefly limited to cattle and sheep, it may be transmitted to goats, horses, cats, and certain kinds of game. Smaller animals, such as mice, rabbits, and guinea pigs, speedily succumb to inoculation. Dogs and hogs are slightly susceptible, while fowls are practically immune. The variety of domesticated animals which it may attack renders it one of the most dreaded scourges of animal life. It may even attack man.

Cause.—The cause of anthrax is a microscopic organism known as the anthrax bacillus. In form it is cylindrical, or rod-like, measuring 1-5000 to 1-2500 inch in length and 1-25000 inch in diameter. Like all bacteria these rod-like bodies have the power of indefinite multiplication, and in the body of infected animals they produce death by rapidly increasing in numbers and producing substances which poison the body. In the blood they multiply in number by becoming elongated and then dividing into two, each new organism continuing the same process indefinitely. Outside of the body, however, they multiply in a different way when under conditions unfavorable to growth. Oval bodies, which are called spores, appear within the rods, and remain alive and capable of germination after years of drying. They also resist heat to a remarkable degree, so that boiling water is necessary to destroy them. The bacilli themselves, on the other hand, show only very little resistance to heat and drying. It has long been known that the anthrax virus thrives best under certain conditions of the soil and on territories subject to floods and inundations. The particular kinds of soil upon which the disease is observed are black, loose, warm, humous soils, also those containing lime, marl, and clay, finally peaty, swampy soils resting upon strata which hold the water, or, in other words, are impervious. Hence, fields containing stagnant pools may be the source of infection. The infection may be limited to certain farms, or even to restricted areas on such farms. Even in the Alps, over 3,000 feet above the sea level, where such conditions prevail in secluded valleys, anthrax persists among herds.

Aside from these limitations to specific conditions of the soil, anthrax is a disease of world-wide distribution. It exists in most countries of Europe, in Asia, Africa, Australia, and in our own country in the lower Mississippi valley, the Gulf states, and in some of the eastern and western states. It seems to be gradually spreading in this country and occurs in new districts every year.

Meteorological conditions also have an important share in determining the severity of the disease. On those tracts subject to inundations in spring a very hot, dry summer is apt to cause a severe outbreak. The relation which the bacillus bears to these conditions is not positively known. It may be that during and immediately after inundations or in stagnant water the bacilli find enough nourishment in the water here and there to multiply and produce an abundant crop of spores, which are subsequently carried, in a dry condition, by the winds during the period of drought and disseminated over the vegetation. Animals feeding upon this vegetation may contract the disease if the spores germinate in the body.

Another source of the virus, and one regarded by many authorities as perhaps the most important, is the body of an animal which has died of anthrax. It will be remembered that in such bodies the anthrax bacilli are present in enormous numbers, and wherever blood or other body fluids are exposed to the air on the surface of the carcass there the formation of spores will go on in the warm season of the year with great rapidity. It will thus be readily understood how this disease may become stationary in a given locality and appear year after year, and even grow in severity if the carcasses of animals which have succumbed to it are not properly disposed of. These should be buried deeply, so that spore formation may be prevented and no animal have

Sheep Grazing on National Forests.

Squelching One Of The Users of Abandoned DE LAVAL Cream Separator Inventions

Our attention is called to the recent advertisement of the Vermont Farm Machine Co., makers of the so-called "U. S." cream separators, which bristles with assertions likely to convey a false impression to those who may have read it.

They refer to the Houston & Thomson patent in a way to imply that DR. DE LAVAL was not the inventor of THE FIRST PRACTICAL CONTINUOUS FLOW CENTRIFUGAL CREAM SEPARATOR, when they know that the Houston & Thompson patent as well as the De Laval patent BOTH belonged to the DE LAVAL Company, that a usable machine was never built according to the Houston & Thomson patent, and that they themselves helped other infringers sued by the DE LAVAL Company to have the courts decide that the Houston & Thomson patent DID NOT show a continuous separator, even in a technical patent sense, let alone a machine capable of practical use.

They say "No discarded or abandoned inventions are used in the United States separators," when they know that since DE LAVAL separators forced them to abandon their antiquated gravity creamers and take up cream separaors they have twice escaped the penalty of infringement suits brought against them by the DE LAVAL Company by narrow legal technicalities alone, such as a patent having been taken out by two men together, one of whom had added to the inventive work of the other, when the American law, different from that of European countries, requires two separate patents being taken out in such circumstances.

And furthermore they know that their so-called "1909 MODEL" machines utilize merely the curved vertical "blade" bowl construction of the NOW EXPIRED NINETEEN (19) YEARS OLD DE LAVEL PATENT NO. 432,719 ISSUED JULY 12, 1890, which "blade" type of bowl construction, while DE LAVAL owned, was NEVER GOOD ENOUGH for DE LAVAL use,—and that any child can see the "new" U. S. utilization of it now by reference to a copy of the patent obtainable from the Commissioner of Patents, Washington, D. C.

They hark back again to a skimmilk "record" claimed to have been made at the Buffalo Exposition in 1901, which has been exploded so often that it's threadbare and at most is a pretty ancient basis to seek patronage upon in this progressive age in the year 1909.

They print a "testimonial" letter from a man who has long been THEIR OWN AGENT, posing as the "president" of a little creamery near Poughkeepsie, N. Y., which letter they have been simply changing the date of and varying a little from year to year for ten years.

While most of this letter is untrue it is true that this agent of theirs did sell a few "U. S." machines to patrons ten years ago, but they were sold at half-price, or less, as a sort of "stage-play," because of the nearness to the De Laval Works, to farmers who were led to believe they were getting "bargains" at the price, some of whom have never used the machines, while others have long ago abandoned their use or traded them in at "scrap" values for DE LAVAL machines.

In this connection it may be remarked that in 1908 the DE LAVAL agents made competitive "trade allowances" for more abandoned "U. S." separators to be thrown into the scrap pile than for any other make of separator, even of the trashy "mail order" kinds, which bears out the judgment of the agents NOW advertising "U. S." separators at "mail order" prices—manifestly putting them in their right class.

We should not devote this much space to the "U. S." machine—which we consider a "dead duck" competitively—but for the fact that this kind of advertising by their makers is more or less typical of that of would-be competitors generally in their desperate effort to keep all 1909 business from going to the Improved DE LAVAL machines.

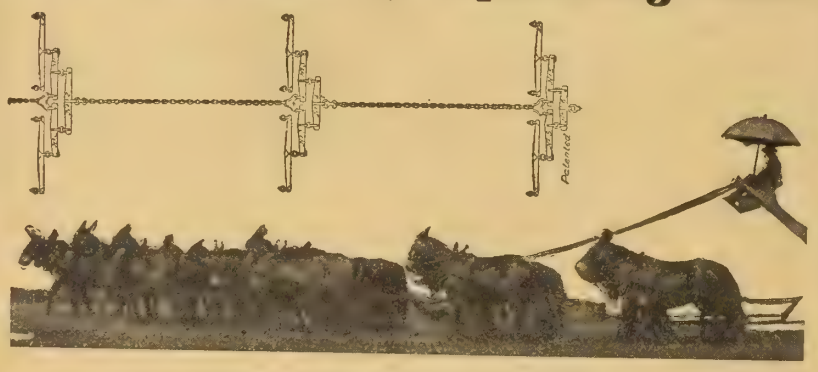
The Schandoney Equalizing Hitch



Positively Prevents Runaways

They are more expensive than these HITCHES. Why take the chances? Anybody can drive, it doesn't require an expert. Over four thousand of these HITCHES now in use, and not one a failure. Write today for further information, Catalogue, etc., to

Schmeiser Manufacturing Company Davis, California

The Frictionless Empire

Have you seen the ballbearing in the Frictionless Empire Cream Separator? If not, you should do so and examine it!

It prevents all wear on the bowl spindle.
It reduces oiling to the very minimum.
It consists of a bushing, through which the bowl spindle passes and this bushing revolves with the bowl on the balls encircling it, thus making it practically frictionless and protecting the spindle from wear, and which helps to make the Empire the easiest running machine on the market. This is only one of the many leading features of the Empire.
Send for catalogue.

access to them. By exercising this precaution the disease will not be disseminated by flies and other insect pests.

We have thus two agents at work in maintaining the disease in any locality—the soil and meteorological conditions and the carcasses of animals that have died of the disease. Besides these dangers, which are of immediate consequence to cattle on pastures, the virus may be carried from place to place in hides, hair, wool, hoofs, and horns, and it may be stored in the hay or other fodder from the infected fields and cause an outbreak among stabled animals feeding upon it in winter. In this manner the infection has been introduced into far-distant localities.—Dr. D. E. Salmon, of the Bureau of Animal Industry.

INCREASED GRAZING ALLOTMENTS.

Material increases have been made on the grazing allotments on the National Forests of California for the coming year. At the request of the Forest Service, the Secretary of Agriculture has authorized the grazing during the season of 1909 of approximately 207,855 cattle and horses, 10,400 hogs and 430,500 sheep and goats within the National Forests of California. The authorization for the season of 1908 was about 185,000 cattle and horses, 6,700 hogs and 426,137 sheep and goats. The actual number grazed during the season of 1908 was approximately 174,900 cattle and horses, 2,584 hogs, and 379,193 sheep and goats. Grazing on the recent additions of the California, Shasta, Modoc, Tahoe and Cleveland Forests will be allowed during the season of 1909 without fee and without permit.

Although climatic conditions were very unfavorable last season the ranges throughout the District carried the usual number of stock through the season without serious injury. This is due to an effort on the part of the Forest Service to restrict the number of stock allowed to graze on the National Forests to the capacity of the range under normal conditions in an average year. It means that in very good years there will be a surplus of feed and at least a reasonable amount of natural reseeding so that in unfavorable seasons the ranges will carry the usual number of stock through in good condition and without injury to the forest. On the whole the stockmen are heartily in favor of the grazing regulations and sentiment grows stronger as local difficulties are adjusted. The fees charged on National Forests are about one-half of those charged on private and railroad lands and less than one-third on an average of those charged on Indian reservations.

PUMPKINS FOR COW FEED.

Pumpkins are an excellent succulent feed to feed milch cows. Of course they will not keep long and must be fed out. Do not let your neighbors dissuade you from feeding pumpkins. Pumpkins contain 1 per cent digestible protein, 5.8 per cent digestible carbo-hydrates and 0.3 ether extract or fat. Rutabagas contain 1 per cent protein, 8.1 per cent carbo-hydrates and 0.2 per cent ether extract or fat. Mangles contain 1.1 per cent protein, 5.4 per cent carbo-hydrates and 1 per cent fat. As the per cent of protein indicates largely the value of the food for dairy cows,

ABSORBINE

Cures Strained Puffy Ankles, Lymphangitis, Poll Evil, Fistula, Sores, Wire Cuts, Bruises and Swellings, Lameness, and Allays Pain Quickly without Blistering, removing the hair, or laying the horse up. Pleasant to use. $2.00 per bottle at dealers or delivered. **Horse Book 5 D free.**

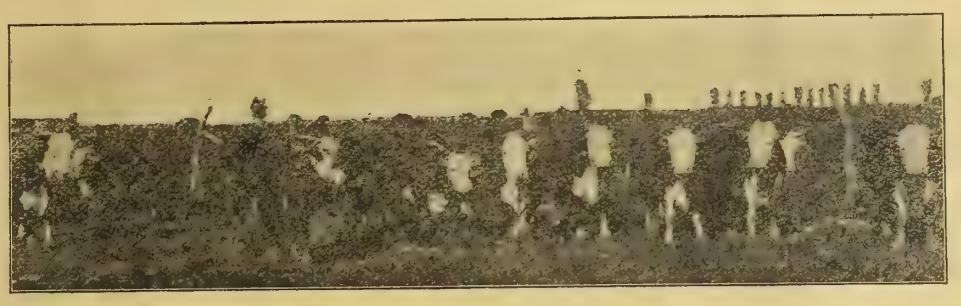
because we have all the carbo-hydrates we need, you can readily see that pumpkins are worth as much, ton for ton, as rutabagas or mangles, and I know of no other succulent food that is relished better by cows after they once acquire a taste for them. It certainly is not policy to feed too many pumpkins any more than it is to feed too many beets. They are valuable largely because of their succulency.

I suppose if one would attempt to make nearly the entire ration for a dairy cow out of pumpkins, the cow would fall off in her milk and it is barely possible that if we should turn the cows into the field and allow them to eat all they care to, some of them would eat so much that it would get them out of condition and off their feed, consequently would dry them up. The proper place to feed pumpkins as well as anything else is in the cow stable.

The Vermont Experiment Station a few years ago made a test of pumpkins and corn silage, and this test seemed to show that two and one-half tons of pumpkins were equal to one ton of corn silage. I think that the growing of pumpkins should be encouraged. A piece of well-prepared land planted to pumpkins exclusively will many times yield profitable returns and they make excellent and handy feed to feed for succulency in the Fall before one cares to open the silo. Some have the idea that pumpkin seeds work on the kidneys of animals as a diuretic and that seeds ought to be removed before feeding them. This, however, is simply another notion. There is nothing in it and the seeds are as valuable as any part of the pumpkin.

With mixed hay and cornstalks for roughage, the grain ration should be rich in protein, because the roughage is quite deficient in it. Corn meal will not balance a ration of cornstalks and mixed hay. We must have some grain ration much richer in protein. You could make a fairly good ration by feeding corn meal and wheat bran and mixing the corn meal and wheat bran in the proportion of equal parts by weight. It would be a more economical ration, however, to mix corn and wheat bran by bulk or by measure and then feed a pound of cottonseed meal night and morning with it. Because you have to buy the grain food, if you have good cows you cannot afford to scrimp them on their grain ration. A cow that is giving a good, liberal flow of milk ought to have from six to ten pounds of grain every day. If it is not convenient to get the cottonseed meal you could substitute oil meal or gluten meal.—Spokesman Review.



Imperial Valley Stock.

CO-OPERATING MILK PRODUCERS.

About a year ago a few dairymen around Artesia, Norwalk and Cypress, Los Angeles county, formed an organization for the purpose of getting a living price for their milk. The buyers in Los Angeles controlled the market to such an extent that they could and did pay what they pleased regardless of the cost of production. This forced the dairymen to either organize and handle their own milk in the city or quit the business.

It has always been said that the farmers could not be held together in any organization even where it was to their interest to do so. That remark is a slur on the farmer and they resent it. They have perfected an organization that assures them absolute independence, and among the tedious process of working out the details, have shown a determination of purpose that cannot fail to win out in the face of the strong opposition that they have encountered on every hand. They have given freely of their time and willingly taken a low price for their milk rather than submit to the dictates of the trust.

The scheme of the organization is so absolutely fair to the farmer whether he produces a thousand or a hundred pounds of milk a day, that there can be no argument against it.

The milk is to be sold in the city and after deducting expenses the balance is to be divided pro rata according to the butter fat. Each member must be an actual producer of milk and can hold but one share of stock. There are to be no dividends, so that there can be no temptation to benefit by manipulating the stock.

From the small beginning a year ago, the growth has been so rapid that today there are over three hundred members, with about 50,000 pounds of milk per day, comprising the Southern Califronia Dairy Association. The Downey Co-operative Creamery Company and the Hynes Co-operative Creamery Association. These three organiaztions are to be operated under the name of the Mutual Dairy Association. The main office will be at 1236 Victoria St., Los Angeles, where the Southern California Dairy Association is erecting a creamery to cost about $25,000, and is to be equipped with the latest appliances for putting the milk on the market in an absolutely sanitary condition.

This is strictly a dairyman's proposition and all are invited to join as the more milk handled the smaller will be the proportionate cost. The stock will remain $100 per share until April 1, 1909, after that date it will advance to $150 per share.

What is really the first great step by the government in the conservation of natural resources is expected to be taken up by the reclamation service in the great Iron Canyon dam in the Sacramento Valley.

PERMANENT ROADS.

The menace to good roads in their destruction by the automobile is demanding more serious consideration than it has ever done. As a rule the farmer appreciates the beneficial advantage of better roads and is submitting in some cases to high taxes in order to secure them. The taxation falls more heavily on him in proportion to the benefits than upon any other industry, but with it all he stands it with fairly good grace.

Unless something is done, however, to lessen the wear on these roads by rapidly moving automobiles, the farmer may be compelled in self-protection to rebel at further taxation. This would not be satisfactory and we trust some plan can be devised to protect our roads from this destructive agency. It is not expected that the automobile may be compelled to disappear to accomplish this because that institution has come to stay, but automobile owners and others must take up the question and help to solve it.

Regarding the destructiveness of the automobile, the Scientific American in a recent issue, comments as follows:

"A serious problem which grows in importance every year is that of the relation of the automobile to the public highways. That the automobile is the most active of all agents in the breaking down of Macadamized roads is a fact that has long been recognized by our state engineers, and of late years it has become evident, that not even the most enthusiastic automobilist can deny that great damage is done. When a new stretch of Macadamized roadway is thrown open to the public, it offers such strong attraction to automobile owners that, even in cases where its use involves a considerable detour as compared with shorter routes over roads of inferior quality, it is certain to become so popular with the rubber tired vehicles that they will frequently constitute the majority of the traffic. The initial breaking down of the carefully prepared surface is almost immediate. The so-called "suction" of the swiftly-revolving rubber tires picks up the finely crushed binding material of the surface, and throws it to the rear, exposing the broken edges of the top course of Macadam. These in their turn are broken down, ground into dust, picked up by the passing wheels, and carried by the wind into the adjoining fields, or sifted upon the lawns and buildings of adjacent property. The process of disintegration goes on at a speed proportionate to the density of the traffic, until finally the heavy underlying foundation rock of the macadam is exposed. When this condition has been reached, there is nothing for it but to practically rebuild the roadway, or at least the upper half of it. The destructive action of automobile traffic has been greatly intensified in recent years by the introduction of chains and other non-skidding devices, which are undoubtedly active agents in breaking down and pulverizing the surface dressing and the upper, broken stone layers of a Macadamized road.

"Finally, as we have frequently pointed out in this journal, our whole system of maintenance needs to be thoroughly revised. Our present methods of allowing a road to go to ruin, and then spreading a layer of so-called top dressing upon it, and calling this procedure a repair job, is simply barbarous. Eternal vigilance is as necessary in the upkeep of a modern highway as it is in that of a steam railroad track. Locl indications of subsidence or wear should be immediately repaired. The constant day-by-day attention of a repair gang, scattered at intervals over a stretch of state highway, will keep the surface in first-class condition for many years. They will do successfully, and for far less cost, what the periodic and spasmodic repairs under our present systems of maintenance fail utterly to accomplish."

'But that all costs—throws a heavy burden on the land owner. As suggested in this paper before, may there not be a license issued to automobiles, the returns from which shall aid in the upkeep of roadways.

CO-OPERATIVE EGG PRODUCERS.

The Egg Producer's Association of Southern California is still engaged in an effort to perfect an organization and to put the poultrymen in a position where they may at least not be compelled to accept dictation, if not in a position to dictate. The poultrymen have just cause for making a desperate effort for this co-operative movement. Their wares have been knocked about from pillar to post on the market and handled at the whim of speculators regardless of rights of producers until there is slight money in the poultry interests.

We recently heard a competent business man who has had experience in the city of Los Angeles in the egg industry for years say that if the producers will stand together, responsible houses may be found which will handle the goods and insure eggs and poultry products always being handled at a fair price, but the fear expressed on the part of the gentleman referred to was that the poultrymen would form such a loose organization that the members should be able to break away from it the moment a little more immediate personal advantage might be secured from parties anxious to disrupt the organization. As the gentleman remarked: "There are large dealers in Southern California who place in storage thousands upon thousands of dollar's worth of eggs." He said: "For instance, I will mention one firm," and he gave the name of a small concern of which we had never heard, and, he added, "This is one of the smallest firms in the city handling eggs, yet it will place in cold storage this year in excess of $20,000 worth of eggs." If this is an indication of the business it may be seen that these men will be anxious to retain the egg handling absolutely in their own power. They can afford to lose money in large quantities for a year or two in order to discourage members of any co-operative organization from remaining true to it. The question now before the poultrymen is will everybody stand up and be true to the organization when outsiders offer prices more liberal than the association will secure when it starts.

We hope the poultrymen will organize and then stand pat.

HORTICULTURAL COMMISSION.

The district attorneys of some counties have seemed to be somewhat muddled as to the situation regarding the old horticultural commission, pending appointment of the board of examiners by the Governor and later the appointment of the single horticultural commissioner. In most counties, however, the district attorney has ruled that the old commission does not terminate until the new commissioner has been examined and qualified.

It is understood that the Governor has appointed the examining board, but at this writing the announcement has not been made as to who will constitute the board. We assume that the examination will proceed as soon as the board has once been appointed and organized.

EAT RAISINS.

The announcement of Raisin Day to be observed on the last day of this month has attracted some attention to the raisin and creating interest which will, we believe, lead to the financial betterment of those engaged in the raisin industry. For instance, Mr. George Robertson of Fresno, has discovered that the people of the United Kingdom eat five times as many raisins as do those of the United States. This is possibly to a certain extent due to a larger amount of fruits in this country of other kinds and the need is not so great for that particular fruit. However, we believe this campaign will attract attention to the healthfulness of the raisin in a way which will increase its consumption not only on April 30th, but many other days thereafter.

CO-OPERATE IN FUMIGATION.

The co-operative movement which we have often referred to in fighting scale and other pests of fruit trees is appearing more and more. In fact it is the one sensible way for the smaller fruit grower. The expense of investing in tents and effective spraying devices is too much for the small orchardist. The contract system has proven satisfactory and again it has proven decidedly unsatisfactory. Some contractors have been doing effective work; others again have only compensation in view. A neighborhood combining to own their fumigating or spraying outfit can by co-operative work, with one good superintendent who thoroughly understands the work, secure maximum effectiveness at minimum cost.

The pests combine against the orchardist, let the orchardist be as wise.

TAX THE GUN.

The suggestion has been made that a tax of two dollars be placed upon all guns, pistols and in fact fire arms of all kinds manufactured or sold in this country as an aid in raising the internal revenue. It certainly would be a satisfactory way of raising the revenue and would place it upon a product which is in no sense a necessity. Many farmers, and in fact others who wish protection in the house, find it desirable to own one or more guns, but as noted they are in no sense a necessity and this tax would perhaps aid in keeping this which is often a trouble maker from the hands of irresponsible persons who at times get into serious trouble from having weapons too handy. If this is done coupled with registering of each purchaser of fire arms we believe it would prevent much crime.

NEXT DEMONSTRATION TRAIN.

Definite dates are not yet fixed for the next trip of the Demonstration Train, but probably a start will be made next week. Our issue of the 15th will give the dates if possible.

Agricultural Notes of the Pacific Coast

Northern California

Anderson, Shasta county, is planning for a rose carnival.

Hop growers are encouraged at the better outlook for the coming season.

One company has planted 11,000 acres to walnut trees at Santa Rosa this season.

The Gridley Herald states that farmers of that section cannot help getting rich.

A coyote bill which passed the recent state legislature offers a $5.00 bounty on every scalp.

During the month of February, San Francisco shipped 115,000 pounds dried applies to Germany.

The recent effort at combination of Luther Burbank with certain capitalists has been declared off.

One packing house in Sacramento has fifty girls engaged in sorting and packing asparagus to Eastern markets.

Hayward reports the fruit blossoming time on the hills thereabout as "A beautiful site in this modern Garden of Eden."

The recently organized Sebastpol growers association has purchased a large building which will be used as a packing house.

The Riverside Creamery at Port Kenyon, Humboldt County, has been purchased by the Central Creamery Company of Eureka.

The field manager of the Sacramento Valley Sugar Company reports extensive planting of beets in the vicinity of Woodland.

Dairymen of the upper Coast counties have suffered heavy losses this year from exposure of stock and lack of housing facilities.

The Government Plant Introduction Garden at Chico is experimenting with the spineless cactus. About five thousand cuttings will be planted.

Asparagus growers of Sacramento Valley are complaining because of its products being shipped from Sacramento under Southern California brands.

Land which was earlier in the season planted to grain crops and then destroyed in the January floods has been planted to sugar beets for the Hamilton factory.

Farmers near Chico predict that that secton will become one of the greatest alfalfa sections of the country. There has been seeded this season over 500 acres.

A scheme to conserve waters for summer irrigation is on foot in the upper canyon of the Feather river. It is practically the building of "bins" for the storing of snow.

Creameries in Marin, Sonoma, Humboldt and Mendocino counties which had expected large government contracts on high grade butter this year have not received them because of prices being higher than Eastern creameries.

G. W. Peavy of United States Service is inspecting lands near Gridley, Butte county, on behalf of the Forest Service and to give advice to a large lumber company which expects to plant these lands to eucalyptus trees.

Central California

Prunes are moving out somewhat more freely.

Santa Clara county cherries now promise an exceptionally good crop.

The town of Exter, Tulare county is discussing the abvisability of incorporation.

Lindsay has rejected shipments of orange trees which came to the station infested with scale.

Tulare has three creameries which are paying to farmers of that section about $75,000 per month.

Orange packing houses are running in Sanger, Fresno county. The fruit is small but of good quality.

The San Joaquin county table grape growers recently held an enthusiastic meeting at Lodi and drew up plans for the proposed grade shipping system.

The Saratoga blossom festival was granted some beautiful weather for its great celebration and immense throngs paid honor to the prune blossoms.

A eucalyptus company with a ranch near Pixely, Tulare county, is planning for setting out 3000 acres of which 1600 acres is to be planted this year.

The Madera county horticultural commission caused the arrest of a fruit seller for selling in the Madera market fruit alleged to be infected with scale.

Saratoga has a committee at work formulating a plan for co-operative fruit marketing. The committee is investigating the advantages offered by the farmers union.

Secretary Blanchard of the Kings county Chamber of Commerce is suggesting that every Californian mail leaflets to eastern friends suggesting the observation of Raisin Day.

The citizens of Fowler are organizing an improvement association which have to do with the best interests of the community and especially with the beautifying of roadways.

Tulare county is somewhat elated over the recent sale of an orange grove near Lindsay where eight and one-half acres sold for $34,000 or $4000 per acre. The trees were all Valencias.

Prune growers of Santa Clara county are working to secure better returns for dried fruit and a committee of fifty has been organized to work out a plan which we hope will be successful.

Biggest sale of fat cattle ever consumated in Porterville section was made recently when a thousand head of steers were purchased by a San Francisco house. The cattle are to be sent in lots of 250.

The grand jury of Tulare county after a short session found no indictments against County officials, but resolved: "Inasmuch as the ground squirrels are growing more numerous each year, and their depredations are so great in many sections of our county as to make farming almost profitless, therefore be it resolved: That we memorialize our board of supervisors of this county to the end that they take some further steps toward the destruction and eradication of this particular pest."

Southern California

Lima beans at Oxnard are now being quoted at $3.55.

Orange picking was stopped by last week's storms.

Orange County's celery crop is practically all shipped.

The Victoria orange packing house at Riverside has installed a new grader.

"Oranges by the peck" is the slogan of the eastern groceryman on the California oranges.

The California Vegetable Union handles over 150 cars out of Coachella Valley each year.

Work has begun on the fire trails of the forestry reserves to clear them up for the summer campaign.

The market has been supplied with new hay; alfalfa especially has been a factor in the earlier sections.

One Orange County cabbage grower has received an offer of $50.00 per ton for a small local shipment.

White frosts with peach trees full of bloom caused some uneasiness last week, but no damage is reported.

Work is progressing actively with the first planting of cotton seed in a large way in Imperial county.

A project is on foot to drain between four and five thousand acres of land near Newport in Orange County.

Oxnard and other Ventura county bean growers are formulating plans for co-operative marketing of beans.

Water users at Escondido are compelled to make extensive improvements on the water system this year.

It is now thought that the crop of cantaloupes in the Imperial Valley will be later in marketing than last year.

It is now estimated that the southern part of the state will ship at least 1,000 cars more oranges than last year.

The Anaheim Walnut Growers Association has agreed to join hands with the Southern California Association.

The grain crop about San Jacinto, Hemet and Winchester will aggregate over a quarter of a million dollars this year.

Oranges which were depressed in price by large shipments after the earlier storms are now recovering their former price.

Imperial county has sent branches of apricot trees to Los Angeles Chamber of Commerce showing fruit larger than large marbles. The branches were cut the last of March.

An orange grower and packer at Riverside has established what he calls "millionare special brand" which will be used on only the finest grade fruit with a special gilt edge pack and only half boxes.

A special train of oranges over the Santa Fe placed its fruit in the market in the Middle West so that the fruit was only seven days from tree to consumer. The train was made up of 35 refrigerator cars.

The recent rains over the southern part of the state came just in time to be of immense benefit to hay and grain growers. The aggregate of the storm varied from one inch to three inches in different sections.

The Coast

Cold storage of eggs has begun at Portland, Oregon.

Vast numbers of homeseekers are entering Western Oregon.

The State Grange of Oregon will convene in McMinnville in May.

Over a million apple trees were shipped into the state of Washington last year for planting.

The dairying industry is developing exceedingly rapid in the Klamath Falls, Oregon, section.

The spring tree-planting at Lewiston, Idaho, is the heaviest that has ever been made in that section.

The criminal court of Dalles, Oregon, had a strange case in a man who stole a whole field of potatoes.

One of the largest and finest stock ranges in the state of Oregon is under the management of a woman.

Farmers of Umatilla county, Oregon, have contracted for a million and a quarter grain bags at 6¼ cents.

The demonstration train for Western Oregon has as one of its exhibits a premium hen which has a record of 256 eggs.

The markets of Oregon City, Oregon, are supplied with wild strawberries which grow on the hills thereabout.

Vast numbers of applications for filings on land recently thrown open for settlement in Western Oregon were made.

The University of Idaho has passed its 500 mark of enrollment. This is the youngest state university in the United States.

A number of stockmen have been arrested for fencing in over 85,000 acres of government land in Harney County, Oregon.

Farmers at Yuma, Arizona, claim eight cuttings of alfalfa per year and that there is no month when the alfalfa is not in bloom.

The Governor of Oregon has recently appointed J. H. Booth of Roseburg, Douglass county, a member of the State Board of Agriculture.

Additions have been made to the National Forest Reserves in Arizona by a proclamation of President Roosevelt prior to his retirement from office.

Hood River section which has heretofore been noted as an apple county, after experimental planting of grapes, will this year plant largely to vineyards.

The demonstration train on the O. R. & N. Railway in Eastern Oregon has as one feature a live stock car in which lessons in judging are taught.

The Inland Irrigation Company at Pendleton, Oregon, is launching the biggest irrigation scheme in that section. It will cover about ten thousand acres of land.

The sheep sanitary commission of Arizona report less scabbies amongst the sheep of the territory this year than usual. This is owing to more general dipping of the flocks.

The largest fir tree in the state of Washington has been cut and will be exhibited at the Alaska-Yukon Fair at Seattle. It is 225 feet long and 14 feet in diameter at the butt.

When the chicks are hatched don't feed them anything for 24 hours, then feed them the best dry Chick Feed you can get. We say that is

West Coast Chick Feed

SAMUEL R. KELLAM, former president of the L. A. Co. Poultry Association, says: "West Coast Chick Feed is the best feed for young chicks I have ever used. I have given this feed a thorough test, and have always found that it produced fine, large, healthy chicks."

MRS. A. BASLEY, the celebrated poultry authority, says. "I want some more of your West Coast Chick Feed, for it is excellent. It is purer, cleaner and appears better balanced than other feed I had been using, and to tell the truth, I have been experimenting, feeding both together, and they always eat yours in preference."

Ask your neighbors, for there is more of "West Coast" sold in Southern California than all other kinds put together. If not sold by your dealer send us $3.50 and we will send a 100 lb. sack, freight prepaid within 300 miles.

West Coast Mill

705-709 So. Griffin Avenue, Los Angeles, Cal.

Profit in the Poultry Yard

By Mrs. Frank Metcalf

We solicit short articles of a practical nature from the fancier and utility breeder, giving their experience with poultry. All inquiries pertaining to feed, management, disease and its prevention will be answered through these columns.

A LAY SERMON ON "LICE."

WE HAVE just had "a time at our house, and nobody to it," and I thought perhaps you would like to hear about it. We pride ourselves upon the fact that we have neither lice nor gapes at Red Feather Farm, and we were much surprised when a few chicks began to gape, and some died. As we have had the wettest weather since the flood, I laid it to old Probs, but my wife simply would have it there were lice about. I cleaned the brooders myself, and protested I didn't see any, or get any on me either, but her manner rather insinuated that I was nearsighted and thick skinned, though she said little.

Saturday afternoon she came home from town with five gallons of cheap lamp oil, and a big bandbox containing a new hat, announcing that "Brother" Scott was to have "an extra good sermon on 'Life and Death' tomorrow."

I rose early Sunday morning and gave those brooders an extra cleaning, while, under instructions from his mother, our boy followed with the spray pump filled with lamp oil. I wondered how I was going to get out of going to church, and finished my job without finding a decent excuse. I was tired, but I knew she would say the music and sermon would rest me. My head did ache, but "Sunday headaches" were worn threadbare, so I just went and lay down, trusting to luck.

Mrs. M. went out to inspect those brooders, and a quick, imperative tap on the window, and a "get up quick, Frank," took me out to see a sight I shall not soon forget.

No lice! O, my eyes. From every crack and crevice of the "middle sized" brooder they were just pouring in swarms, fat, hearty looking chaps, and millions of them. I had no idea they would go near a tarred roof, but there they were as well as everywhere else. My wife was sprinkling oil over the outside with a rose sprinkler, but could not reach every spot. We opened the door of the lamp chamber, (lamp had been out a few days), and found them bunched in swarms there, the lamp chimney itself being completely covered with crawling mites.

Well, Brother Scott's sermon and the new hat were forgotten, and we waged a battle of life and death right there in the shelter of low branched trees which hid us from the view of neighbors passing by on the road to church and home again before we were through.

My brooders are made detachable, so the tops were tipped back off the platforms, giving us a good chance with the spray pump and lamp oil. The hovers were taken out and sprinkled thoroughly, and last the floors were well covered with road dust. The five gallons were soon used up, the house oil went next, and even the large parlor and kitchen lamps were emptied. My wife did cast longing glances at the bedroom and sitting room lamps, as well as the lanterns, but thought of the baby in time to save them, for that small person objects to darkness, and stays awake rather late. Only the one brooder was found in this shape, but all were dosed as a preventive, and gone over in much the same way last Saturday, a week later, and very few were found. How those chickens lived and throve as they did was a mystery to us.

I believe in keeping the chicks off the damp ground at night, but the platforms are separate so the tops can be tipped back allowing them to be cleaned, sunned, and aired easily, and are well sprinkled with road dust after each cleaning.

I found earlier in the season that raw eggs were superior to cooked ones for small chicks, and corrected bowel trouble even after some were caked up behind. I mix one-third bran to two-thirds corn meal, and wet with the raw egg. Believe all food for chicks should be raw, not baked, boiled or scalded. Have raised a larger percentage of those hatched this year, so fed, than I have ever been able to do before. Fed no meat, but lots of milk. They have grown and feathered very quickly.—F.M.

POULTRY QUERIES.

Possibly Poisoning.

We read with interest your department, and would like very much to have these questions answered: What is the cause of chickens, apparently healthy and laying well, to suddenly droop their heads when on the roost, so that the head hangs down below the feet, and die in a day or two; without power to lift their heads?

We had a dozen young chickens, have been laying several months, all apparently perfectly healthy, but have lost four hens and a nice rooster, all in the same manner. One large R. I. Red rooster and two hens yielded to treatment of melted lard with a little formoloid (Wampoles), and hot milk given from a teaspoon and recovered, but the others treated the same way, died. They have free range on new lemon grove, (year old trees), and have free access to stable and manure pile of four head of stock. Get all the crushed barley they can eat, green feed in orchard and part of the time wheat. Do not seem to have cold.—Mrs. E. A. H., Charter Oak.

These symptoms point strongly to poison of some kind, and the fact that part of them recovered from the treatment given, almost proves it. Either these fowls did not get so strong a dose as the others, or your treatment was administered in the nick of time. It looks like ptomaine poisoning and a post-mortem might have helped to discover the cause of death. Perhaps gopher poison had been placed somewhere or they ate the poisoned animals. Perhaps they obtained some poisonous food intended for vermin of some kind or it may be the trees were sprayed, and the grass under them affected. It acts very like "limber neck" which is caused by decayed meat, usually, although putrid milk is quite as dangerous. Worms sometimes affect poultry badly also, and an occasional dose of sulphur in a mash, say a teaspoon to a dozen birds, will help rid them of these parasites.—Mrs. F. M.

Geese Dying.

I had a fine goose get broody, and set her in the corner of the hen

WATER GLASS FOR EGG PRESERVING

Why sell eggs at 15c a dozen? Eggs kept in this water glass will keep 12 months or more and are as fresh as new laid. Sold in 25c tins for 150 eggs and $1 tins for 1200 eggs. Egg preserving baskets with cage and cover $1 each. There is only one kind of water glass suitable for this purpose and it is on sale at West Coast Seed Co., 115 West Seventh St., Los Angeles.

Wm. C. Parker, 111 Pacific Avenue, Santa Cruz, Cal.

house, on a board floor with a straw nest. Her mate was put in with her at night. In three days I noticed the droppings from the gander looked white, and very watery, also he appeared weak, and didn't eat. I thought it cholera, and gave him the remedy I have used successfully with chickens, namely, a teaspoon of camphorated oil; I also gave him a liver pill; he is apparently all right now. The goose appeared to have watery discharge from her nostrils and eyes at the time I began to doctor the gander. I took her off the nest and she could scarcely move from weakness. There appeared to be small spots like dry blood around the root of her bill. She also had white watery droppings. I gave her some of the oil, and a quinine pill, thinking she had a disease like roup. In about 12 hours I gave her another pill, and covered her with a sack of burlap, also gave her a lot of straw. She lived about ten hours, and died on the nest. Now I have another laying goose showing the symptoms of running at the nostrils, and eyes, and somewhat weak, sits around and doesn't eat. I thought she caught cold last night, as she was out, and it rained. Today and tonight I have her in a corner in the hay in the barn where it is warm. I treated her like the gander, but don't know whether I will bring her out or not. Any help you can give me will be greatly appreciated. I have just begun with geese, and no one in this locality seems to know what I can do for them.—Mrs. G. E. C., Escalon.

Without knowing how your geese were fed, it is hard to tell just where the trouble lies, but I should suspect a grain diet, from the symptoms. Geese are grazing things, and too much grain will kill them by indigestion. They should have a grass run, or plenty of green food at all times, or it is next to impossible to keep them in health.

Little grain should be fed them at any time, and that should be corn on the ear part of the time, and if roasted brown in the oven, helps their digestion, when impaired.—Mrs. F. M.

HINTS IN USE OF WATER GLASS.

Water Glass in tins will keep good for years, but when diluted with water is only serviceable 12 months. Fresh glass should be mixed each year.

Barrels, earthenware jars, galvanized or iron buckets, and cement tanks in the ground, are all suitable for egg storing.

Eggs have merely to be dropped into the water glass, and allowed to rest in any position.

Egg vessels may be stored in any temperature, outhouse, cellar, pantry, back or front rooms, or even attic, although a moderately cool and even one is best.

Eggs a week old will preserve well, but do not come out as fresh as when put in the day they are laid.

Eggs may be taken out of the glass water at any time during the year for use or for sale, and others put in their place, and glass eggs will keep fresh for a month or more after they leave the glass water.

All water for diluting the glass is best boiled, as it destroys all germs and prevents thickening of the liquid.

The vessel need only be half filled with liquid, which rises as the eggs are put in, and the cover is only to keep out dust and retard evaporation.

Water glass is harmless to both hands and clothes and is non-poisonous. It is a powerful antiseptic. The glass acts only upon the shell of the egg, making it air and water tight.

Glassed eggs for sale should be rinsed in warm water and wiped dry. They will then be as clean and fresh looking as when taken from the nest.

Coulson's POULTRY FOODS

Special Dry Chick Food

Makes Them Grow

COULSON'S SPECIAL DRY CHICK FOOD, during the five years it has been on the market has justly earned for itself its great reputation as a life-saver for little chicks by its special adaptation to their needs.

THE UTMOST CARE is observed in the selection of each of the dozen or more articles composing this unequalled feed; tender seeds, cracked grains blown free from dust, steel-cut oats, tiny pieces of dried meat and bone, willow and pure bone charcoal, are combined with other very necessary ingredients; every article being selected with special reference to its quality, strength, and desirability for the needs of the young chick.

FOR YOU TO BUY the many different articles composing Coulson's Special Dry Chick Food is quite impracticable; you could not be certain as to their quality for one thing, and the high cost of certain of them when purchased in small lots might lead to their being left out to the detriment of the chick.

TO MAINTAIN the high reputation of COULSON'S SPECIAL DRY CHICK FOOD, nothing is left undone to make it absolutely the best feed that can be made for the little chicks.

COULSON'S SPECIAL DRY CHICK FOOD can be fed exclusively to your little chicks for the first six weeks, at a cost of about four cents (4c) each; and what is of still greater importance, it will do all that can be done in the way of feed to bring them through that critical period of their lives in full health and vigor.

TO RAISE EVERY CHICK you hatch; to have fine, large, healthy chicks; to have chicks that will stand up and crow when eight weeks old; to raise chicks that you will be proud of, FEED COULSON'S SPECIAL DRY CHICK FOOD, THE LIFE SAVER.

Manufactured Only By

Coulson Poultry and Stock Food Company *Petaluma, California*

GERMAIN SEED CO., Distributing Agents, Los Angeles, Cal.

A few cracked shelled eggs put into lime water make the whole batch of eggs to go bad, but in the case of water glass the other eggs are in no way damaged by the presence of the cracked ones.

The cost of preserving eggs in glass is only five cents per hundred in large quantities, or eight cents per hundred in small quantities.

The egg pails with cage are not a necessity; they are merely for the convenience of people who object to the wetting of their hands in the glass water when abstracting eggs from the vessel. Any ordinary bucket will preserve eggs equally well.

THE HOUSING PROBLEM.

How to keep chickens well and healthy is a great problem of poultry raising. With colds, gapes, swell head, etc., the business is one that yields small profits and great perplexities, even disappointments both in feelings and finance.

Too many people have an idea that chickens, do not need to be dry and warm as do the humans. They must be comfortable, even in this land of the Southwest, where it is "perpetual" summer. It is a mistake for either people or poultry to try and live on the ground or in damp cool rooms.

My first experience in poultry was the cause of much sadness and many tears. My chief trouble was colds, swell head and roup. I bought enough antidotes, food preparations, medicines and tonics to have stocked a pharmacy. I dipped and I doped all to no purpose. My beautiful darlings died by the dozens. With dogged determination I held on to the remainder and hoped for better luck.

Luck.

There is, however, no such thing as luck in the chicken business, at least as long as the low squatty houses are used with no floors and with strong odors arising from droppings, which are constantly inhaled by the fowls. At least if there is such a thing as luck, it is bad luck.

My mother never had roupy chickens and she had large roomy houses. Her perches were arranged to rise from the floor like a stairway to the higher parts of the house. Her success was such that I have set about building my houses on the same plan, only that the droppings can be cleared from the floor with greater ease. I had the floor laid with a slope towards the front, ascending perches and descending floor.

The doors open so that the attendant could enter and scrape or brush, or even wash, if necessary, the descending slope of the floor. The housefront was outside of the chicken yard, which carried this manure entirely away from the poultry.

Since making this change I have had absolutely no more sick chickens, but, I have had many, many more eggs and that too when I have been able to sell them at 60 cents per dozen.

I may add that I fed corn all through the molting period, and that my hens were hatched in the fall and winter. This I think had something to do with my hens laying so well when eggs were at a high price.—Mrs. E. M. Stetson, Lankershim, California.

Mrs. Stetson sends a drawing, showing the method of arranging floor and perches. We think we can describe it, however, by saying that the highest part of the floor and the

lowest one of the perches come nearly together. From this point the floor slopes strongly downward to the front of the house, which is outside of yard. The ascending perches carry the birds so they go near the top, as far as possible from the dropping board. The uppermost perch goes within about two feet of the roof.

TRAP-NEST IN EGG-PRODUCTION.

A trap-nest is a simple device to catch the hen when she enters to lay. As she passes into the nest she presses against a trigger which holds up the door, and it falls down behind her, says the Farm World. When she has laid, the egg is numbered to correspond with the number on the hen's leg band. This enables the breeder to keep each hen's eggs separate with perfect accuracy.

Attempts to improve the egg-producing qualities of the hen date to the domestication of the hen, but it has only been within the last few years that rapid progress has been possible in this work. The inability to determine the good layers has been the difficulty.

With the perfection of the trap nest this difficulty has been removed and many poultry breeders are now engaged in the production of egg-laying strains of fowls.

The great majority of people make no selection of hens from which to hatch their stock. The eggs of the whole flock are kept together and when eggs are desired for hatching they are selected from a general basket.

It has been assumed, and is shown by trap nest records, that eggs thus selected in the spring of the year are from the poorer rather than from the better layers.

This is because the hens that have not been laying during the winter will lay very heavily during the spring season.

Trap nests revised to catch the hen that lays the egg are numerous in the market. A trap nest to be successful must not only catch the hen that lays but must prevent the entrance of other hens.

The more trap nests that are provided, the less often they will require attention, but the more often the nests are attended the better for the comfort of the hens.

A GOOD ROOSTER.

A Tampa man who believes in chickens moved recently into a locality where the fowls run at large. He had none, but he built a nice little roosting house in a nice little pen. He bought a handsome Leghorn rooster, kept him up and fed him well until he became used to the premises. He then opened the gate of his fowl yard and let the rooster go out foraging around. That night he brought home with him a following of three hens, which the shrewd man shut up in an adjoining enclosure. He sent the rooster out every day for a week and robbed him of his gains on his return home every night. He has now so many hens that he has had to buy another rooster and he keeps his fowl yard jealously closed day and night. He is thinking of writing for the poultry magazines a long and convincing treatise showing that it pays to keep chickens.

Antelope Valley was covered several inches deep with snow during the recent storm.

UP-TO-DATE IMPROVEMENTS IN CREAM SEPARATORS.

Cream separators come and go—every year some new names and some that are heard of no more—but all appear to have little effect upon the firmly established prestige of the "World's Standard" De Laval machines, which were first in the beginning and which their makers have spared no efforts or expense at any time to keep in the van of all attempted competition.

Some of the radical changes made in the new 1908-9 machines are mentioned: The capacities were increased from ten to twenty per cent. The supply can is now low enough to meet the objection that has sometimes been made to the lifting of milk into it. The bowls retain, the distinctive "Alpha-Disc" and "Split-Wing" tubular shaft De Laval features, but have been scientifically re-designed, from engineering considerations. The bowl is more sanitary in its construction, being free from tubes, wings, orifices, or any parts which are not easily unassembled. The supporting spindle now sets well up under the bowl, at the center of weight and balance. The top bearing, which provides the yielding cushion the bowl spindle must have, is most ingeniously simple, hardy and inexpensive.

A new feature which appeals to every housewife is the drip shelf coming between the frame and the stool and catching any oil or overflow of milk and water, that might otherwise run to the floor.

In the reconstruction of the machines every part has been carefully designed with reference to its extreme simplicity, not only of itself but in its assembling with the other parts with which it must fit, and it is said that the new machines have been completely unassembled down to the last part within five minutes of time, by persons who had never touched a separator before, and then completely reassembled again within ten minutes without the slightest trouble.

The new machines have been the subject of much favorable comment by Experiment Station and other authorities and many experienced users of separators, have come to appreciate some of the difficulties they had to contend with before and some of the new features which it seems hard to be without once it is known that they can be had.

More than 15,000 users of old machines—various other makes as well as antiquated De Laval—are said to have availed during 1908 of the small "trade" allowances which the De Laval Company makes for such old machines, and it is confidently expected that a still larger number will do so this year.

A FINE TESTIMONIAL.

Williams & Son send us a copy of a testimonial, one of many received, in regard to their cultivator advertised on another page.

Merle, San Diego Co., Cal., March 25, 1909.

Arnott & Co.,
Los Angeles, Cal.

Dear Sirs:—You may recall that I recently purchased one of your Williams Goose-Neck Cultivators. I wish to say that I am exceedingly well pleased with it. In fact, as I told Mr. Jones, your representative in Oceanside, I would not take $500.00 for it if I could not get another. This is not an exaggerated statement, I mean it literally. In this section we do not have irrigation and everything depends on proper cultivation, so that good tools are very important. There are three points in which the Williams Goose-Neck Cultivator surpasses all other cultivators which I have seen, viz:

First. The draft is very light. My two horses weigh 900 lbs. each and they have no difficulty in drawing the 7 ft. cultivator.

Second. The Williams Goose-Neck Cultivator stirs the soil well without exposing the subsurface, thus preventing the escape of moisture.

Third. The cultivator being of low construction, one can cultivate under the trees as easily as harrow.

I was showing my cultivator to a neighbor the other day and had him take it home to try it. The use of it for half an hour so thoroughly convinced him of the merits of the tool that he has, through Mr. Jones of Oceanside, given you an order for one-half dozen cultivators.

Messrs Williams & Son of Orange, certainly deserve great credit for inventing the Goose-Neck Cultivator.

Sincerely Yours,
LOUIS C. LUHR.

SAVES LABOR.

Button Willow, Cal., March 6, 1909.

Mr. John Schilling, Jr.,
Los Angeles, Cal.

Dear Sir:—The Auto-Fedan Self-Feed Hay Press I bought of you last season is the only self-feed I ever saw that would feed. It makes such nice square bales, no danger of the wires slipping off at the end even if they are loose. I have baled three tons per hour at ordinary rate of speed. My team came off at end of season in good order.

Other presses use from four to six horses, and they are nearly worthless at the end of the season. Also the low table is very convenient for baling from the buck rake, saving much labor. My neighbor, Mr. Phillips, saw mine and says he wants one this season.

Yours truly,
C. W. ROWLEE.

Write Jno. Schilling, Jr., agent; call Davies Warehouse, Los Angeles, Cal.

Thousands of Chicks

Hatching every week, send today for new 1909 Baby Chick Catalog, tells all about our 19 kinds of chicks, ducks, turkeys, etc. Also about our low prices on all kinds of hatching eggs. We ship chicks and eggs everywhere safely. Now is the time to order. We supply 50-chick "SUCCESS" Fireless brooder at $2 and 150-chick brooder at $4, if you order it filled with chicks. Ask about this today.

IRRIGATE FROM YOUR OWN RESERVOIR

A reservoir on your own land makes you independent on the water question. You will have no trouble in filling the reservoir during the spring rains, when all the streams, little and big are flooded.

Then you will not be at the mercy of ditch owners and other water users when the dry season comes.

The few acres you will require for the reservoir will not be wasted. They will serve to make all your other lands vastly more valuable.

Raise the Water With An I. H. C. Gasoline Engine

Of course you cannot have your reservoir on your high ground. Locate it on the bottom land where it is easiest made and certain to be filled with drainage waters.

Then pump the water wherever you need it with an I. H. C. gasoline engine. These engines, always powerful and reliable, have been found to be excellently adapted to irrigation pumping.

They are operated with little expense. They require but little attention.

They enable you to utilize the waste waters such as deep streams, sloughs and ponds upon your own land.

The farmer who has a water supply of his own, so that he may irrigate a few hours now and again, without regard to whether the water is flowing in the company ditch, is the independent farmer.

A reservoir on your own land and an I. H. C. gasoline engine to give you the water when you want it, where you want it, is the solution of the problem.

The I. H. C. gasoline engine can be used for other purposes beside pumping. It is a general purpose engine, which will be found an all around handy farm helper —to run grinder, sheller, separator, fanning mill, washing machine, churn, grindstone, etc. The I.H.C. line includes besides Famous pumping engines and jacks, the following:

Stationary engines, from 1 to 25 horse-power; Portable engines, from 2 to 20 horse-power; Skidded engines, from 2 to 8-horse-power; Tractors, 12, 15 and 20-horse-power, and Sawing and Spraying outfits.

Call on the International local agent for catalogs and all particulars in regard to these engines, or write nearest branch house.

Irrigation and Forestry

CARING FOR THE ELECTRIC MOTOR.

OF ALL the power-giving engines invention has ever produced, the electric motor requires the least attention. It will run under all sorts of discouraging conditions for days and days, and even years, with absolutely no attention beyond an occasional oiling. But, while the electric motor is a very rugged machine, it will, like any other machine, suffer from abuse and neglect.

The life of a steam or gas engine is a matter of a few years but an electric motor will run practically forever if it is well oiled. Motors, even after being the victims of fires, floods and other disasters, have been cleaned up and set running just as good as before.

By observing the following hints, says one of the General Electric engineers, electric motors will do their work long after their owners are dead.

Grazing on the high mesas of Arizona.

The electric motor should be kept clean. Keep all dust and superfluous oil wiped off. See that the brushes bear firmly and evenly on the commutator. Occasionally wipe off the commutator with a cloth upon which a few drops of oil have been placed.

If for any reason the commutator gets rough, smooth it down with a piece of fine sandpaper. The commutator, when operating under the best conditions, will assume a gloss of light chocolate color.

See that the oil rings in the bearing revolve freely, and occasionally draw the oil off from the reservoir, clean it out with gasoline and refill with fresh oil.

After the brushes have once been set for sparkless commutation under normal load, they should not be changed.

In starting a motor, move the starting lever of the rheostat forward slowly and steadily. Never try to stop a motor by forcibly moving the rheostat lever backward. Always open the main switch first.

Occasionally feel of the various connections. If one is heated it indicates a loose joint and should be remedied at once.—Electric Journal.

LEGISLATION TO PREVENT FOREST FIRES.

The frequency and seriousness of forest fires during the past autumn prove that the present laws for the protection of the forests are inadequate. We are of the opinion that negligence or inexcusable carelessness is responsible for the majority of the fires, not merely in the Adirondack regions, but also in the fire-swept districts of Minnesota, Michigan, and Wisconsin. If this carelessness be measured by the magnitude of the disasters of which it is the original cause, it takes on surely a strong flavor of criminality. For it is no excuse to say that the hunter who fails to extinguish his campfire, or the settler who leaves the edges of his clearing burning through the night in proximity to inflammable forest timber, does so without any thought of the loss of life or property which may result from his carelessness; for he is well aware of the fact that such smoldering fires may, and do, start great conflagrations, and that in these conflagrations it frequently happens that not one but many human lives are sacrificed. If such carelessness in the presence of this knowledge be not criminal, a new definition must be found for this last-named word.

Our attention has recently been drawn to the fact that in Canada there is a strong movement on foot, urging the government to follow a more definite course of action in the protection of the forests, and to make the breach of the forest-protection laws punishable by imprisonment without the option of any fine. The object aimed at by the suggested legislation is, not merely to increase the number and enlarge the powers of the forest wardens, but also to compel every camper to either extinguish his fire or keep it under guard; to require every settler, railway contractor, or railway, in clearing lands, to maintain a guard by night as well as by day, so long as the stumps are burning, and to prevent any stumps or underbrush being fired within a reasonable distance of the standing timber; and finally, to make the railways and factories whose tracks or works are within the forest area responsible for the protection of the forest to a given distance on each side of the railway track or factory.

We commend this subject to the attention of the legislatures in those states most nearly affected. It is certain that legislation bringing the careless starting and neglect of fires within the range of the criminal law would prove a most speedy and effective check upon the present annual destruction of life and property. —Scientific American.

Some grain is still being sown in eastern Monterey county.

Bees and Their Care

BEE PARALYSIS.

A LADY apiculturist writes under a late date from a post office of the San Diego hinterland that two of her 18 colonies of bees are dying. They come crawling out of the entrance, she says, bloated of body, go along a little ways and then lean over and die. There are handfulls of them in front of the hive, all having died within a week. They are not starving, nor can she determine any other cause responsible for the trouble. "Is there no help for it?"

Another beekeeper located in an alfalfa growing region is also "alarmed" over the prevalence of this same disease in his extensive apiary. He has been told that re-queening will cause it to disappear, but he finds that re-queening at this time of the year is no easy matter—as, indeed, it is not, if one is to rear one's own queens.

This matter seems fully worth while to take into public print; not merely because of the two cases mentioned just now, but because of the large number of others, for there is probably no apiary of, say 40 colonies or over on the coast that does not show one or more cases of the same trouble, sometimes, but lightly developed, but sometimes badly.

In the Spring.

The disease appears mainly, and almost only, in the spring time. It is not contagious, and healthy colonies, though closest neighbors, locally, are in no danger of catching it because of such neighborhood. But as it makes the colonies affected unprofitable for the season unless speedily cured, it is clear that a considerable spread of it, numerically, may cut down the revenues of an apiary considerably, even disastrously.

In Europe it is known as the "May disease," and is there attributed to the reaction new nectar and pollen produces in the organism of bees confined all winter on some inferior kind of honey, or honey-dew.

Hence they have there developed the practice of extracting all but about one-half of the honey needed for winter stores, and then supplying the other half with sugar syrup fed late in the fall. Much practice in this matter has given them great faith in the wintering quality of sugar syrup. It might be a good plan where paralysis is very bad to try the same thing in this country.

Easy to Determine.

The symptoms of the disease make a certain diagnosis an easy matter. In a case of foul brood, or pickled brood, or black brood only an expert can distinguish which is which, or whether any disease is present at all, or not. Touches of foul brood may come, and go, and the apiarist never know it. The deeprooted instinct of self preservation seems to endow bees (as other primitive creatures) with a wonderful wisdom at such times to find in the open and to apply the remedies needed.

If broodrearing is in full swing all around, a paralytic colony may at once be known by the great extent of its nest. It would seem that, knowing that a heavy percentage of its population must inevitably fall a prey before field work can be entered upon by them, they attempt to make the continual loss good in the only way open to them, i. e., extensive brood production. But besides that the rapidly accumulating mass of dead and dying bees just in front of their home will tell the unmistakable story of the nature of the trouble. True, in a heavy nectar flow, like that of the orange, for instance, the place just in front of a strong colony is often a scene of like or similar, commotion, that is, of great numbers of wiggling and slow moving bees. But in the one case the movement is away from the hive, and in the other toward it, that makes the radical difference. And then, also, at closer observation, the bees offer bodily a different sight. Both the diseased and the nector laden ones show the telescopic segments of their hinder parts drawn out the full length, but the first looks greasy and never behaves in the business-like fashion of the latter. And then there is that alternating tremor of its limbs that leave no doubt of the kind of bee under observation.

Driven Out.

Sometimes a stricken bee comes dragging herself out of the entrance by herself; to get away, probably, from the intense activity inside, but more often two or three others, healthy ones, will push and drive her out, in the relentless fashion known to natural history students the world over. Once out there, and left alone, the pitiable little thing starts every little while to drag herself a little farther, but soon lapses again into rest. And bye and bye, a few hours, or a day at most, the little spark of life fades away, her limbs stiffen, slowly she keels over, and all is still.

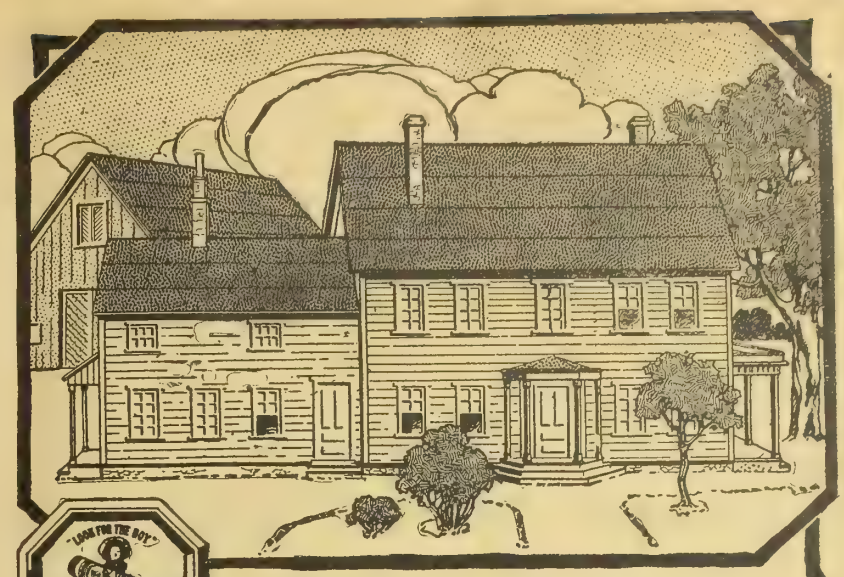
That is paralysis.

As to Cure.

And the cure? Of all bee diseases this one is the easiest to cure, and the simplest. A perusal of the technical literature might, perhaps, suggest the contrary, but a fair trial of the method given below will establish proof.

The first warm sunny noon that happens, go to your diseased colony, take off the lid, give just enough smoke to drive the bees on top of the frames below, then sprinkle about one-half ounce of finely pulverized sulphur over the frames. Shut up the hive warm, have a small entrance, and then leave them alone for three days. After the expiration of that term repeat the operation as before, and if you can spare a frame of hatching brood from some healthy colony give them one, putting it into the middle of the nest. Repeat this second operation in three days to prevent a relapse. For the disease itself, though seemingly cured as early as the fifth day after commencement of treatment, has latent possibilities of recuperation. As soon as any ways handy, give them a young queen, and by the first of May the former eyesore of your apiary will give you double joy—partly because of its healthy activity, but mainly, because the forthgoing of the nursing instinct of the humane spirit in you is granted the spiritual award of almost creative work as your eyes linger upon the pleasing scene.—Henry E. Horn, Riverside, Cal.

A Petaluma rancher recently killed a big California lion on his ranch near that place.



All Farm Buildings

should be roofed with REX—the all-round roof. It keeps the house warm in winter and cool in summer; it protects poultry from damp and extremes of temperatures; it guards stock and produce from wet; it defends buildings against the communication of fire by falling sparks and firebrands.

REX FLINTKOTE ROOFING

is made of long-fibre wool felt treated by our special process. It contains no tar or paper. Heat will not soften it, nor cold crack it. It is laid as easily as a carpet. Everything but the hammer is in the roll.

SEND FOR FREE SAMPLES

We will send upon request samples to test, and our valuable roofing booklet. "Look for the boy" on every roll. See trade mark in upper corner.

Harrow While You Plow

Make one job out of the two, and get your ground in finest condition by harrowing when the soil is first turned up.

KRAMER'S Rotary Harrow Plow Attachment

enables you to do this. Regular rotary harrow which attaches to any gang or sulky plow. It levels, pulverizes and makes a mulch of the "moist soil" that is not possible after the ground dries and "sets." Draft only slightly heavier—you'll be surprised to see how little. Everybody needs this great time and labor saver. Write for circular No. 84

Deere & Co., San Francisco, Cal. Mitchell, Lewis, Staver, Portland, Ore.

FREE TRIP TO SEE THIS HAY PRESS AT WORK

LOS ANGELES AND RETURN AT OUR EXPENSE

WE PAY YOU TO INSPECT THESE HAY PRESSES.

Instead of paying a salesman's fare to show you a small model of a hay press, we will pay your fare to Los Angeles and return, not exceeding $15.00, to examine our California Special New Century, full circle, all steel, self feed Hay Press and all others on sale there. It makes no difference which hay press you buy, we pay your railroad fare just the same.

When you see for yourself how this machine has been built expressly for heavy baling on the coast, how strong it is, how easy it is on horses, what smooth bales it turns out, you will understand why we make such an offer. It has 7-in step-over, pull power, high baling chamber, positive plunger rebound; it stands up to its work, no taking off of wheels. Has record of 39 tons per day. We will ship you one to try. If you don't want it we will pay freight both ways. Write now.

Queries and Replies

Questions to be answered in this department should be received at this office one week before reply is expected. Write plainly on one side of the paper and sign full name and address. Unsigned communications receive no attention.

Australian Onions.

I have some Brown Australian onion seed left over from this season's planting. I am thinking of planting this seed in July or August—about two months earlier than I generally plant in beds. Would I get stronger, better plants, or would it be too hot?—W. W. P.

I know of nothing to be gained by planting the Australian Brown so early. It is wanted for the fall and winter market and planting in July or August would bring it in ahead of time. It is not the kind of an onion the market calls for in early and midsummer. The White Queen would be a better variety for such an early crop.—Q. A. L.

Violets—Roses.

I transplanted my violets last August. Previous to transplanting they bloomed nicely, but while they look well now and are growing and spreading they do not bloom. Some of my roses develop to only about two-thirds and then get rusty and black looking and drop off. Both violets and roses are well fertilized with horse manure that has been well rotted.—J. J. F.

This seems to be a case of too much nitrogen with the violets. So much manure induces a growth of an abundance of foliage instead of blooms. They will likely do better later on and certainly next season, when they will have somewhat exhausted the soil. Withold the manure for another season.

It is difficult to get perfect blooms on the roses during such a winter as the past. The mean temperature has been too low. On the approach of warmer weather one may expect better results. It is an error to try and get roses from the same plant the entire year. Allow the plants to rest the latter part of the summer by withholding water and late in the fall or in the early winter cut back very severely and fertilize well in February and March with stable manure. This treatment will give an abundance of fine blooms from April to July.—Q. A. L.

"Beer Seed."

Before the civil war, while residing in the southern states, we had a plant that grew under water which was called "California Beer Seed" from which we made a very good tasting home-brewed beer. Since coming to California in 1875 I have never encountered the California product nor do I know what that vegetable growth was which made good beer every day by adding a small quantity of molasses and enough water to make a day's supply. Will you kindly inform me what that vegetable was and if any of it is now grown in California?—W. F. H

We do not know and have been unable to learn from many whom we have inquired what beer seed may have been. Will our subscribers inform us, if there are those who have ever grown this seed.

Hillside Grass.

What kind of grass is best to plant on a hillside too steep to be farmed with success. We want to put something there for permanent pasturage and as the soil is good and the rainfall abundant in this section, it seems as though there ought to be something that would do well. Would paspalum succeed there? Is there any kind of leveler or roller that would do well on a steep hillside? Even a harrow slips down hill in vineyard work.—Mrs F., Santa Cruz.

This question is one of the hardest to answer which comes to the office, and similar ones come often. The plant which will give luscious, abundant feed without irrigation in California is usually scarce. Under the conditions which our subscriber gives, we believe we would try alfalfa as an experiment. It is probable that large returns would not be had, but we have seen alfalfa grown on the hillsides where the rainfall was abundant and the hill rose above the field in question so as to give considerable moisture to the sub-soil. We would try the paspalum. The inquirer asks as to how rye grass and esparcet or a German clover will do. We cannot learn that this last-named grass has been grown to any extent, though it has been in this country for the past 150 years. Where it has been tried it has not been giving satisfactory results, but Prof. Bailey suggests that inoculation with beneficial bacteria may secure more satisfactory returns. It seems that it is a plant that requires well drained soil if under irrigation. Under proper conditions it is in no sense equal to alfalfa. We know of no roller or leveler which will work on a hillside without sliding down.

Eucalyptus.

I have ten acres of sandy loam sub-irrigated. I wish to plant, if profitable, to eucalyptus, and how should the seed be planted? How may I procure the proper varieties of seed. What varieties would be most profitable?—Subscriber, Newman.

If our subscriber has ten acres of good sandy loam near market, subirrigated as he states, we believe it to be too valuable to give up to timber culture. However, in that section, if he wishes to get good returns from this valuable timber—if the temperature never goes below 17 or 18—it is probable that the blue gum would be the best variety. At least it has been tested and known to do well in this state and to be a most valuable lumber. Different varieties of seed may be had of any of the seedmen advertising in the Cultivator.

Now is the Time to Plan for the Future

Write for free illustrated catalogue and kindly mention the "Cultivator."

Girdled Orange Trees.

In working about my orange trees, I find a half dozen that have been completely girdled by gophers, some being 12 or 14 inches above the roots. Bark has been entirely removed.—A. B., Sanger.

If as soon as discovered the trees had been treated by packing with mud and kept moist continually until healed over, it is probable the new bark would have formed by granulation. After this time, however, and if the wound has dried over and the wood hardened, the only plan of saving the trees will be to use small scions cut from the top of a thrifty tree and these used to in-arch between the bark at the roots and above the wound. By doing this and making careful cuts so as to bring the inner layer of bark against the inner layer of bark of the old tree, it is possible the trees may be saved. Four or five scions, or even more, may be used around a good-sized tree.

Peanuts.

What kind of soil is best for peanut culture? Will they do well in this climate? When should they be planted?—L. L., Yolo County.

The peanut requires a light, sandy soil, one which will not pack after irrigation. The time to plant is when the ground is warm and the danger of frost passed, depending on locality. Plant as you would beans as to depth.

Fertilizer Spoiling.

Please tell me whether any kind of fertilizer will spoil and how long they will keep.—B. P., Los Angeles.

We hardly know what our subscriber means by "spoiling." Nitrate of soda gathers moisture and may possibly leach away if near the coast or where the air is filled with moisture. Any fertilizer, stable manure, or whatever it may be, if exposed to the rain leaches away and loses its fertility by that means. Stable manure when exposed to the sun loses much of its nitrogen and humus. Commercial fertilizers, however, sacked or carefully preserved under cover, so far as we can say, would be as good ten years from now as today.

Sour Orange Seed.

May sour oranges be planted any time in April for nursery stock?—A. J. B., Calexico.

Yes, April is a good month in which to plant orange seed. Plow or spade the ground thoroughly and deeply. Seed may be broadcast or drilled as you prefer. After seed is scattered, cover to the depth of an inch with sand which has been thoroughly screened, or before the sifting of the sand the seed may be covered with a thin layer of very fine garden soil. This will hasten the germination process and keep the moisture better than does the sand alone. Of course it would be necessary in your section to protect trees carefully against the burning sun. The lath house or cotton cover will be necessary for this.

A large number of queries appear this week, the answers of which have been delayed by illness of Mrs. Sherman.

Forcing Cows to Dry Up.

I have two cows coming in the last of April. They are giving two gallons a piece each day. How can I dry them off quickly? Should a heifer coming in with her second calf be milked right to the time of calving? I take the Cultivator and think highly of it. —A Subscriber, Long Beach.

Rub the udder with camphor water and leave the last of the milk in each time say half a pint and the cows will dry off rapidly. No! only when the cows do not fall below four gallons a day of milk do we milk them right up to calving time. Ordinarly cows do not make all the year milkers and are not injured by forcing dry.—M. E. S.

Garget.

My Jersey has been fresh since the 1st. of January and only one teat appeared to have a large flow of milk. The milk from the other three teats were thick and sometimes cheesy and very yellow. She is in fine alfalfa pasture with plenty of alfalfa hay to eat at night. On examining the udder we find each teat that is not giving good milk to be hard or lumpy pretty well up into the udder. Now what will we do to relieve that and bring them back to their milk. We keep them milked out dry and there always seems to be some milk coming in from the three teats. She will give a little over a pint each milking while from the good teat she gives a good gallon. The bad milk is quite clear at night, but in the morning gets thick and cheesy when we milk.—Desert Farmer.

This cow has had garget. The teats that do not give good milk may possibly be helped by injecting them with warm water containing a teaspoonful of baking soda to each quart. After five or ten minutes milk out the teat as clean as possible. The udder may be rubbed well with warm lard, rubbing for five full minutes and kneading it gently. Even if these teats should not straighten out this time, the next time she is fresh they may come all right. The feed has little to do with garget, but it is the result of cold or of bruising by rough milking. —M. E. S.

Possibly Cow Pox.

I have heifer which has been giving milk about eight months, her teats have changed color from white to dark purple and keep scabbing and pealing off. She is continuously kicking at her sides. Can you tell me the cause, and remedy.—M. D., Imperial.

Probably cow pox, this should be treated by rubbing on some bland ointment or vaseline to heal them up. Should there be any indication of infection or pus a perioxide water should be used first and then the vaseline. Some times a dusting of powdered charcoal is all that is needed to heal these teats. I should use a milking tube until the trouble is better, for the heifer must suffer considerable pain when milked.—M. E. S.

Grapes Not Bearing.

Have about two acres of Emperor grapes, a few vines bear well every year, the rest are very light bearers. They all bloom and make a strong growth, I used to sulphur twice—first in bloom—second when as large as shot. The last two seasons have sprayed them with Rex and some with bluestone with the same results. Pruned long, five to seven buds on a spur—from three to five spurs to a vine, of course according to size. I tied to a three or four foot stake. While this variety is light, Tokays and Cornichon in the same field bear well.—H. S., Weimar.

The first place these Emperors are pruned rather shorter than usual. The vines should be on six-foot stakes and pruned to five feet tops, with spurs all the way up from the first eighteen inches from the ground. As the heads are formed with these vines, I should, if they were mine, put a single wire from stake to stake and extend out one arm two to three feet on each side of the vine and then prune the laterals back to three buds on arms, in this way giving the vine more chance to grow. The Emperor however is a peculiar vine and some strains are not fruitful. The above is given as a suggestion, not as a sure remedy.—M. E. S.

Sorghum.

Will you please advise me when to plant sorghum for silage to be mixed with Indian corn; also as to preparing the land. How deep to plow and distance rows should be apart. Seed per acre and best seed to plant.—C. E. G., Hynes.

Sorghum is planted as soon as frost danger is past. The plant is only delicate at first and the old roots often go through a season coming up the next year as bright as ever. It is always a slow grower at first and seems discouraging, after it is a foot high however it makes one rub his eyes. It grows so fast that you fancy you are dreaming not seeing the field that you looked at last week.

The land is plowed and harrowed smooth and the sorghum put in with the corn planter in continuous rows, each row three feet apart. The land is kept cultivated between the rows and all weeds kept out. The early Amber is the regular variety and is found in any of the large seed houses. The sorghum may be cut when it is three feet high and if not cut below the lower joint it will come up quickly again and make abundant feed. After each cutting irrigate and cultivate.—M. E. S.

Summer Manure Crop.

I observed in a recent "Cultivator" that you speak of growing green manuring crops in your orchards during the summer season.

I would feel much obliged if you would kindly state what variety of legume you find most satisfactory.—W. B., Orange.

The Black Eyed bean and the common cow pea. These do best with us in the heated season and the black eyed bean we find fully as desirable as the cow pea and often the seed is more readily obtained in this market. —M. E. S.

Sorghum For Shade For Poultry.

Would you advise me to plant sorghum in the chicken yard as a shade from the hot sun and a protection from the wind of this part of Arizona? Do you think chickens would be as liable as cattle to be poisoned by the prussic acid in the stunted plants? Would it serve as green feed for chickens?.—Subscriber, Douglas, Arizona.

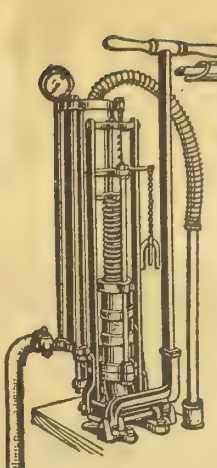
That prusic acid is a remote source of danger as far as we know has never been found in California. The few times it has occured in the East are practically not enough to cut any figure. If sorghum grows with you it would certainly furnish feed, but it is a slow grower at first and if I were going to use it for the purpose of shade I should plant some kafir with it. This Kafir corn and milo maize have not had the tryout they should in this state, I believe from the way they have stood hardships in this ranch that they will be found valuable in heat and drought.—M. E. S.

Plant six pounds of seed of either sorghum or kafir corn, in drills, to the acre.

Essex Hogs.

Please let me know if there are any breeders of thoroughbred Essex hogs near San Jose.—C. P., Campbell.

We do not know of any breeder of Essex in that section, but if any of our subscribers of Santa Clara county do, will they kindly inform us.



Saves One-Third the Labor

Wouldn't you like to cut your labor expense an even third? You can do it on your spraying —and this advertisement tells you how. What's more, the work will be done more quickly and better. Use

Bean Magic Spray Pumps

The Bean patent spring (shown in the cut), divides the work; the operator does half at each stroke of the handle, and works against but half the pressure indicated on the gauge. Bean Magics are built in two sizes; both have non-clogging ball valves, porcelained cylinders, and other exclusive Bean features. They're the easiest running, least troublesome pumps on the market.

Our illustrated catalog No. 21 describes ten sizes of hand pumps, and contains much valuable spray information and formulas. Catalog No. 22 describes Power Sprayers. Both books sent free. Write for our special offer; mention number of acres and kind of fruit.

General Agriculture

GROUND LIMESTONE FOR ALFALFA AND CLOVER.

Eastern farmers are finding that limestone is necessary to best results from alfalfa and in many papers we note reference to its beneficial results. California soils are generally very rich in lime so that the grinding and use of limestone will probably not be resorted to. However, we clip the following from Hoard's Dairyman:

The conviction is being forced very rapidly that a dressing of two to five tons to the acre of ground limestone has a splendid effect on alfalfa and clover. Indeed, in many instances, where these plants were unsuccessful to a large degree, such application brought them forward in fine growth.

The reason for this is found in the fact that the soil had become too acid to allow the bacteria these plants need to develop. In a great many instances, in the older farming districts, the soil has become acid. Of course the farmer is not aware of this important fact unless he has tested his soil with litmus paper. Should he make the test, he will be surprised to find that those fields, where alfalfa or clover do not do well, will show acidity, particularly a foot or so below the surface. This is the reason why the ground limestone makes such a change for the better.

Then, besides, both clover and alfalfa are very greedy for lime. We have noticed, in several instances, where alfalfa was flourishing finely on some high knoll, where the lime rock nearly cropped through, when in the lower and richer parts of the field, it did not do well. Now, it is a simple, practical thing to supply this ground lime rock. The material is not expensive, costing about 60 to 70 cents a ton. Then again, in any section where limestone abounds, it would be practicable for a few farmers to invest, say a thousand dollars, and buy the rock grinding machines and thus supply themselves with an abundance of this valuable material.

Acidity in the soil affects all crops more or less. If it can be cured by such simple means, why not set to work in an enterprising way and do it? Everywhere that it has been tried fine results are reported. Hoard's Dairyman farm is expecting to try a carload of the ground limestone next spring. It should be scattered on the surface of the land when ready for sowing or planting. We plow under the phosphate with manure, but apply the limestone at the surface so that its sweetening effect may take place, as it dissolves and leaches down in the soil. The rock is ground to a very fine powder.

The Orange County Celery Growers Association has signed a contract with the California Vegetable Union for another year's marketing of its celery under conditions same as last year's contract.

WHAT IS THE DAVIS BILL?

The bill provides for an annual appropriation of about $9,000,000 for instruction in mechanic arts and home economies in secondary schools of towns and cities with above 2,000 population. Instruction in agriculture and home economics in 300 to 400 agricultural secondary school, one in each district of not less than 5 nor more than 15 counties. A branch of the experiment station of the state at each agricultural secondary school.

The national appropriation is restricted to studies in agriculture, mechanic arts and home economics in the respective schools. States and school communities required to pay for buildings and other studies.

Each incorporated city, town or village with more than 2,000 inhabitants will receive 10 cents per capita for instruction in mechanic arts and home economics. The total rural and village population will receive 10 cents per capita for instruction in agriculture and home economics in agricultural high schools, practically one in each congressional district.

Each state will receive one cent per capita annually, to be used by its state normal schools to prepare teachers to teach vocational subjects.

Each state must divide its territory into district of 5 to 15 counties, and to establish in each a high or secondary school of agriculture and home making, with a branch of the state experiment station.

Each state and territory to receive one-fourth as much money for branch experiment stations on its agricultural high school farms as it receives for these schools; and is required to appropriate for the use of these branch stations at least as much as the United States Treasury provides.

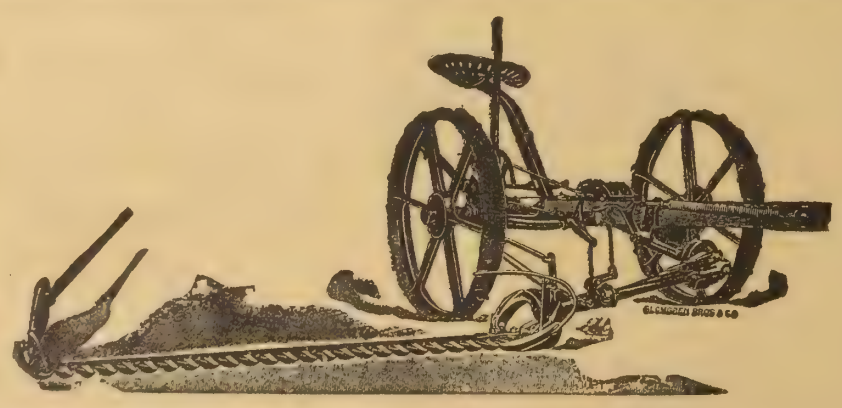
Then follow provisions for the administration of the law, which will not be of interest until enacted, and schools are about to be established. It will be seen that this is a very elaborate comprehensive, even ambitious educational scheme. It is not proposed, it seems, to make the system obligatory upon states; any state can adopt it if it cares to assume the expense, which will be little or much according to the number of schools established. The kind of education it is proposed to give is highly important, since it will teach how to do things as well as how to know things, a sort of education which should be common to all schools.

If the experiment stations provided for are to be such in the same sense that state experiment stations are, this feature of the proposed law is unfortunate. Experimental work, to be of any practical value, involves research or scientific ability of a high character, which manifestly is not attainable in the quantity that a multitude of stations would demand. If, on the other hand, by experiment stations is meant practice stations or grounds, where field work may be made to supplement agricultural classroom work, then the proposition is all right.—Exchange.

The lemon growers are pleased with the possible increase on tariff on lemons from one to one and a quarter cents.

The Cost of the best Mower is lower than the cost of the cheapest Mower at the end of one season's use.

The best Mower gives the best service all the time.



The New Standard Mower

TIME AND LABOR-SAVING DEVICES and DEVICES FOR PREVENTING FRICTION found only on the NEW STANDARD MOWER.

The floating cutter-bar provides a frictionless channel for the knife and prevents wear on the guards. The guards are protected by chilled reversible rails, found only on the NEW STANDARD. Sixty cents will replace an entire set of rails on a five foot bar. To replace only two guards on other mowers will cost as much.

All shafts run in detachable sleeves and there is no wear on the main frame. The benefits of this construction more than warrants the cost.

A force-feed cup grease oiler is part of the pitman box. The screw cap is held in place by a spring and cannot work loose. One turn of the cap supplies ample lubricant and overcomes hot boxes and delays incident to the use of fluid oil. Hours are saved during harvest (when hours mean money) by this device, found only on the NEW STANDARD.

These are only a few of the prominent labor and time-saving devices which decrease the operating cost and add to the life of the NEW STANDARD MOWER.

Our illustrated Hay Tool Folder describes these features in detail and also tells why the New Standard Mower is the Easiest Running, Most Powerful Cutting and Longest-lived Mower made. Write for the folder today.

Imperial Valley, as it was. Courtesy Calexico Chronicle.

GRAIN WEEVIL.

The best way to destroy the grain weevils in your granary is to fumigate with carbon bisulphide. The building must be made, as nearly as possible, airtight. Use one pound of the carbon bisulphide to every 700 feet of space, or one pound to every 100 bushels of grain. The liquid should be placed in shallow pans or dishes as high in the bins or building as possible, since the vapor is heavy and settles to the lower parts. The liquid should be well distributed, having not more than a half pound in a place. Allow the building to fumigate from twenty-four to thirty-six hours, after which open and air thoroughly. Caution—The vapor of this liquid is highly inflammable and explosive when ignited. No fire or light of any sort should be allowed about the building while the fumigation is in progress.—Farmer.

DRY FARMING.

While the Dry Farming Congress is in a sense a new organization its importance as an economic movement is easily estimated from the fact that when the irrigation water has all been impounded statistics show that water can be placed upon but one-ninth of the available and well-located agricultural land. Even the most skeptical critics of the effort to populate the unirrigated lands are now beginning to admit that in the face of their constant claims that failure would surely follow attempts at so-called "dry farming," the crops from unirrigated farms—both experimental and operative—have "made good" the claims of the "dry farmers."

Supervisor Slosson of the Santa Barbara Reserve has issued over 200 grazing permits. The range is reported in excellent condition.

Imperial Valley soil produces this kind of corn after $400 per acre had been taken off of it from cantaloupes if water is applied

Harness leather becomes hard, brittle, unsafe, when the pores in the leather are open to wind and moisture. An application of

EUREKA Harness Oil

fills the pores, seals them against these hardening, rotting agencies and keeps the harness a beautiful black, soft, elastic, and tough. Eureka Harness Oil does wonders for a harness. Ask your dealer.

TO "THE MAN WITH THE HOE."

A generation ago, Samuel Allen was tilling his land in the same way as all the rest of the farmers. He was a good farmer, and he was not satisfied with doing the work in the slow back-breaking way it had always been done. He wanted bigger results, without working so hard to get them. He knew what kind of tools he needed, but there was nothing but the old-fashioned farm implements that had always been used, so he started to make implements for himself that would help him do the work of his farm. His neighbors soon saw how easily he did his work and how he actually got larger crops with less seed. The first thing he knew, his neighbors were borrowing his implements to do their own work with. Seeing that his neighbors thought so much of his implements, Mr. Allen determined to make more and sell to his neighbors. He started, and has been at it ever since. His "neighbors" kept constantly increasing in numbers, until they reached from the Atlantic to the Pacific, and from the Gulf beyond the Lakes; and he was compelled to manufacture on an extensive scale.

Mr. Allen calls his implements the "Planet Jr." from the resemblance of certain of the implements to the planets revolving around the sun.

Mr. Allen's ingenuity shows itself in every one of the forty-five kinds of Planet Jr. Farm and Garden implements, which he makes. For instance, the No. 25 Planet Jr. Hill and Drill Seeder, Double-Wheel-Hoe, Cultivator and Plow combines every useful garden tool in one strong, light, easy-running, simply-adjusted implement that does the work of three to six men working in the old-fashioned way.

The results obtained with these implements are simply marvelous compared with old-time methods. Their merit and popularity is shown by the two million users of these implements at the present time, and the enlargement of the factory which has been made necessary to supply the increasing demand. S. L. Allen & Co., of which Mr. Allen is head, is the organization which now makes these implements, and they have issued a new 56-page illustrated catalogue of Planet Jr. implements for 1909, which they are sending free to those who write to S. L. Allen & Co., Box 1106 P, Philadelphia, Pa.

Household Department

DON'T KNOCK.

Don't think yourself a censor for the silly human flock,
And just remember as you go, that any fool can knock.

Don't laugh at those who make mistakes and stumble by the way,
For you are apt to follow them—and almost any day;
Don't think the others shifting sand, while you are solid rock,
And don't forget, for heaven's sake, that any fool can knock.

Don't be a puller-down of fame on other men conferred,
Don't give a parting kick to one who fell because he erred.
Don't think that you are perfect and the only size in stock,
And now, once more, just bear in mind that any fool can knock.

—Becktash Bugle.

A SLIGHT MISCALCULATION.

THE young man with the beetling eyebrows and the assertive necktie paused to knock the ashes from his pipe.

"Who'm I going to take to the theater party?" he echoed. "Why, I don't mind telling you that I'm going to take Ethel!"

"Oh!" said the other young man whose quietness was his noticeable characteristic. "Have you asked her?"

The young man with the necktie looked faintly surprised. "How'd you know I hadn't?" he inquired. "I'll telephone her tonight. I was so busy all day I didn't have a chance. Besides, there's no hurry. There isn't anyone else likely to ask her but you, and now that I've spoken first of course—"

"Why, of course!" agreed the quiet young man. "I shouldn't dream of interfering with your plans."

"That's one thing I like about you," confided the young man with the tie. "Some fellows don't know when they're licked, but you've got common sense. Oh, I was just speaking generally. There are fellows, you know, who'd 'a' sneaked off and phoned Ethel before I'd had a chance. Of course, though, I don't know that you're so awfully keen on going with her yourself, only you've gone to see her a lot."

"Yes, I have," agreed the quiet young man.

"I've been so busy lately I haven't been around to see Ethel as often as usual," said the young man with the tie. "I expect she's sore about it, but this theater party and some flowers and candy'll fix things all right! I know girls!"

"You do, indeed," agreed the quiet young man. "She was speaking about you only the other evening."

The young man with the tie tried to look unconscious. "Was she?" he asked carelessly. There was a silence. "Say," he broke out at last, "I don't mind telling you—we're old friends and you are sort of one of us, you know—I don't mind telling you that I'm going to marry that girl!"

The quiet young man stirred into surprise. "Ethel?" he queried, explosively.

"Uh-huh," said the young man with the tie. "I expect you are kind o' surprised. I flatter myself that I don't let on to the general public just what I intend to do, but I've been thinking it over for a long time and I've decided she's the girl for me!"

"Oh!" said the quiet young man more calmly. "I see. You—you haven't asked her, then?"

An Imperial Colt.

The young man with the tie shook his head.

"Are you going to telephone?" his friend inquired with innocent interest.

The young man with the tie looked a trifle suspicious, but decided that nothing was meant by the question.

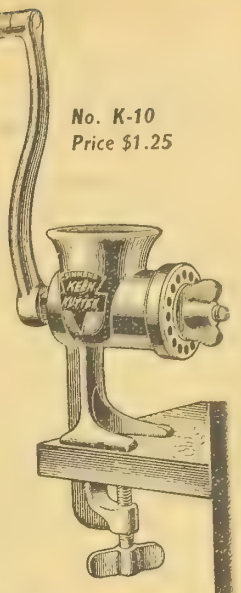
"Well, no," he admitted. "I hadn't thought much about it. I didn't decide till just recently. I'm not going to jump into a thing like that in a hurry and be sorry ever after. I know what I want in a wife. Now, Ethel is not too pretty, you see—she can't be vain about herself, and a vain woman is always selfish. I abominate a selfish woman! All she thinks about is herself and her own comfort. I want some one who'll consider me first. It's right that the man who provides the home and works for it should be considered first!"

"I see your point," said the quiet young man.

"Some fellows never think of those things. Ethel isn't everlastingly chattering, either. She would give a fellow a chance to do a little talking himself. Most girls think the only thing of importance is what they have to say. Did you ever notice how Ethel will sit and listen with her head

Less Work— Dainty Dishes

No. K-10
Price $1.25



No woman realizes how much work she could save, and the tempting variety of dishes she could offer at the table, until she possesses a Keen Kutter Food Chopper.

Just a few turns of the handle instead of the tiresome chop, chop at the chopping bowl. Meat, fish, vegetables, fruits are chopped uniformly, coarse or fine as you wish. The

KEEN KUTTER

Meat and Food Chopper

is attached to the table or detached in a second—works so easily a child would enjoy using it—wears a lifetime—more easily cleaned than a chopping bowl.

Sold under the famous Keen Kutter name and trademark, which always and everywhere guarantee satisfaction or money returned. Ask for the Keen Kutter Food Chopper by name.

If not at your dealer's, write us.

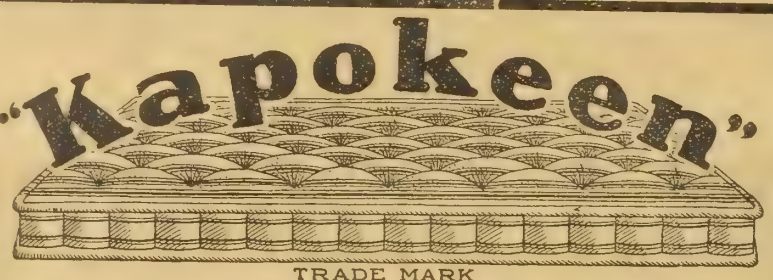
"Kapokeen"



TRADE MARK

The Mattress of Quality

In introducing our Kapokeen Mattress to the readers of The Cultivator, we are taking the first steps toward establishing a National reputation and market for an article, which, on account of its many advantages, has gained a pre-eminent position in its own vicinity.

"Kapokeen" is made from the Kapok or silk floss obtained from the bean of the Eriodendren tree, grown on the island of Java. It is prepared by our own patented process, which removes every particle of seed and preserves in full the resiliency of the natural fibre.

The mattress is made in our own factory where every precaution has been taken to insure absolutely hygienic conditions, by skilled workmen using only the best quality of materials throughout.

NOTE THESE POINTS.

Kapokeen can be "made over" in exactly the same manner as hair.

Kapokeen is sun dried, sun cured, and free from chemicals or other foreign substances.

Kapokeen, no matter how long it has been in use, by being placed for two hours in the sun, will expand and become as resilient as a new mattress.

Price *No. 1 Kapokeen Mattress, 4-4 size, 5 1-2 inch box, Imperial edge satin ticking* **$15.00**

Three-Quarter Size, $12.50 *Single, $10.50*

Kapokeen Mattreses are made only by

John Breuner Co

A postal will bring you a little booklet describing this mattress

Angle Lamp

The Light That Never Fails

Thousands in use all over the country. A good light is the greatest pleasure and the first necessity of every home.

The only lamp on the market that is sold under an absolute guarantee.

Remember, the light from Kerosene is the light science has agreed upon as being the purest and best, because it is soft and mellow and restful to the eyes.

Here are a few of The Angle Lamp Merits:

NO UNDER SHADOW. NO SMOKE, NO ODOR, LITTLE HEAT. GREAT ECONOMY—COST LESS TO BURN than an ordinary lamp. As easy to operate as gas or electricity, and better than either. ABSOLUTELY SAFE under all conditions. Lighted and extinguished like gas. Burned HIGH or LOW like GAS without a trace of odor. And a BRILLIANT, soft, steady, shadowless light—but this you will have to see to appreciate.

The lamp as shown in cut burns 22 hours on 3 quarts of oil.

one side, as if she was so interested—kind of amused?"

"I don't believe I ever did," said the quiet young man.

"Perhaps not," said his friend with the assertive tie. "You probably haven't had as long talks with her as I have. She always listens that way when I talk. That girl is intelligent, and when she gets a chance to listen to conversation that's worth while she does it without interruption. I think she's economical and a good housekeeper. Don't you?"

"I have great admiration for Ethel," declared the quiet young man, "but I never exactly figured out her good qualities as you have done."

"Well, that's natural; you didn't have the idea in mind that I did," said the young man with the tie.

"No, indeed I didn't," said the quiet young man with a fervency that caused his friend to look puzzled.

"You see," went on the quiet young man as he got into his coat, "I believe if I were you I'd not waste a nickel telephoning Ethel. She promised to marry me a week ago and I rather think she expects me to be her escort to that theater party. Good night."

The young man with the violent tie sat staring at the chair which had been occupied by the quiet young man.

"I'd like to know," he said at last, "just what it was she said when she spoke about me the other evening! Come to think of it, I believe his tone was sarcastic when he mentioned it!"

About the House

SOMETIMES when cooking asparagus, before the tough stringy ends are sufficiently tender, the delicate tips are done to ruin. This may be avoided by cuting the stalks all of equal length, and fastening them securely, after which they are stood upright (stalks downward) in a kettle of boiling water, the water coming two-thirds of the way up to the tips. Now adjust the cover closely and boil for about thirty-five minutes, the tips being cooked by the steam alone. Every particle of a bunch of asparagus may be utilized. The coarse ends make a delicious cream sauce or soup, while portions of the vegetable left from a previous meal may be converted into endless salads, souffles, etc.

An asparagus "rabbit" or "rare bit" may please some of the Cultivator readers. Lightly toast and butter thin rounds of whole wheat bread, covering each with a thin layer of cooked asparagus, cut in minute pieces; sprinkle with salt, paprika, a few drops of Worcestershire sauce, and a liberal coating of grated American cheese; cook in a hot oven sufficiently long to melt the cheese, but not brown it. Serve immediately with a poached egg arranged on the top of each portion.

One cook's way of cooking rice is to wash the rice in several waters before putting it in a kettle of bubble-boiling water, previously salted. Cook it rapidly in an open vessel; when every grain is swollen and just tender, pour it into a colander and let drain; after which place in oven to dry for a moment. If served as a vegetable it is then ready for the table. If you want it for a dessert or breakfast cereal, heat milk and add to it a beaten egg, flavoring and sugar, and pour over the rice.

A friend dropped in the other day and told me of a "new salad" that she had learned to make while visiting in San Diego this winter. Grind or chop very fine equal parts of celery and carrots and a very little onion. Heap on lettuce leaves or cress and cover with mayonaise. "It is easily made and very good," according to my informant, who is an experienced cook.

In an old scrap book under the head of "Puzzles" I found this,—"If you want to find the age of a friend, without asking him outright, do this way. Give him a piece of paper and a pencil. Tell him to put down the number of the month in which he was born, then multiply that number by two, add five, multiply by fifty, add his age subtract three hundred and sixty-five and then add one hundred and fifteen. Then ask him what the last number is. If he has made no mistake in his work, the two figures at the right will be his age, and the one, or the two at the left will be the number of the month of his birth." I thought perhaps some of the boys and girls would like to try this.

Some household hints that may be of use were found on the "household page" of a southern paper.

Rubbing butter on the lip of a cream jug will keep it from dripping, and greasing a saucepan will keep the contents from running over so easily when cooking.

One good biscuit maker makes her dough very soft, simply patting it into shape on the board before cutting.

There is only one right way to do up white ribbons which have become soiled. Lay the ribbon on a table and scrub it, using soap and water, and a brush with stiff bristles. When cleaned, rinse beneath the spigot, squeezing out the water between the fingers without creasing the material, and hang over a line. When dry, the ribbon will be found free from wrinkles and fresh looking as when new.

If in ironing you scorch an article, soap suds and the hot sun will remove it.

Use strong baking soda water for scald or burn where the skin is not broken.

Brush the stove pipe over with equal parts of kerosene and linseed oil when put away for the summer.

White lead is an excellent cement for mending china. It may be bought at any shop where art paints are sold.

To clean bath tubs put salt in a dry cloth and rub the soiled parts, or dampen the cloth with coal oil—and you will find the tub easily and quickly cleaned.—Elbepe.

JUST FOR THE GIRLS.

If you want an umbrella to use to save your best one, and have a good frame with a worn out cover, you can easily make a new cover for the frame from black sateen or any preferred material . Rip off the old cover and cut out one section carefully along the seams for a pattern, then lay this on the cloth, the lower edge on the selvage, and cut the pieces without allowing for seams, as the new goods will stretch a good deal. Baste carefully and stitch on the machine, then stretch smoothly over the frame and finish the top with a ruffle of ribbon and tack the covering in place with stout thread.

In washing kid gloves, the kind that can be washed in soap and water, wash them carefully then rinse them

in clean soapy water, so that a little of the soap is left in the kid to keep it soft.

Fine white waists made of sheer material and nice handkerchiefs and neckties need very little rubbing if they are put to soak in a borax solution before washing in suds, and it should be used in the proportion of a tablespoonful of borax to a gallon of water.

If you want a safe and excellent tooth powder, mix well together equal parts of powdered borax and gum myrrh, and rinse the mouth out night and morning with warm water in which a little borax is dissolved, as it strengthens the gums and removes tartar, and disagreeable odors and use the borax solution as a gargle night and morning to keep the throat in a healthy condition.

Clean lace woven or fine silk stockings by washing and rinsing in naptha but it should never be used in a room where there is a fire or light.

White lace or chiffon veils may be nicely cleaned by soaking for half an hour in a solution of white soap and warm soft water and then pressing between the hands until clean. Rinse in clear water, then soak in very weak gum arabic water a few minutes, then shake and pull gently in the hands until nearly dry and then pin to the bed or over some smooth surface until perfectly dry, and veils can be kept fresh looking until they are nearly worn out.—M. H.

Mountain Forest Scene.

A BREAKFAST PROFESSORSHIP.

Those who believe that a good substantial breakfast is the best beginning for a day's work—and those who hold with Emerson that pie is a good breakfast food, will be interested in a clause in the will of a New England man who left a good round sum "to any academic institution that shall first raise a like sum for the endowment of a professorship for the purpose of inculcating in the young a love for breakfast; to stay the tide of anti-breakfastism; to teach by precept and practice the dietary fallacy of coffee and rolls as sufficient nutriment for the beginning of the day's toil; to restore to popular favor that ideal of breakfast foods—pie; and, in general, to lead the race away from the influence of pseudo scientific dietaries, that future generations may recover the mental and moral virtues and the physical strength of their forefathers.

The Pomona cannery has decided not to can tomatoes the coming year.

THE WOMAN AT THE BOTTOM OF IT.

"It's my idee," says Uncle Ned, "that
purty nigh every growed-up human
Belongin' to the sterner sex has kindly feelin's toward a woman.
And yet how many men will say—an' jest as if they sort o' love it—
When some weak mortal goes astray,
'A woman's at the bottom of it!'

"I calculate I've been around about
as much as anybody
Observin' all the ways o' folks, an' after purty careful study
It's my conclusion that the men secure 'bout all the credit due 'em,
While women as a rule don't get the praise that should be comin' to 'em.

"Just take the leaders o' the world—
they'll tell you in some way or other
The strength that made 'em win their fame was borrowed from a wife or mother.
An' if the truth is ever known—the hull truth—how they got so noted—
Jest lots of statues made fer men will be rebuilt an' petticoated.

"I don't maintain all women folks are
perfect, an' I've never said it,
Yet I believe they're doin' good for which the men are gettin' credit.
An' when I see a monument with
some man's figure up above it,
I think that jest as like as not a woman's at the bottom of it."
—Nixon Waterman.

LITTLE BOY'S PRAYER.

Dear God, I need you awful bad;
I don't know what to do;
My papa's cross, my mama's sick;
I hain't no fren' but you.
Them keerless angels went and brung,
'Stid of the boy I ast,
A weenchy, teechy baby girl—
I don't see how they dast!

Say, God, I wish you'd take her back—
She's just as good as new;
Won't no one know she's second-hand,
But 'ceptin' me an' you;
An' pick a boy, dear God, yourself,
The nicest in yer fold;
But please don't choose him quite so young—
I'd like him five years old.
—Lippincott's.

WATCH THEM WELL.

There are four T's too apt to run
'Tis best to set a watch upon:
Our Thoughts.
Oft, when alone, they take them wings,
And light upon forbidden things.
Our Temper.
Who in the family guards it best
Soon has control of all the rest.
Our Tongue.
Know when to speak, yet be content
When silence is most eloquent.
Our Time.
Once lost, ne'er found; yet who can say
He's overtaken yesterday?

Eggs and Poultry.

Eggs declined a cent after last week's quotations, but the Easter demand began to stimulate the market and a two cent advance was made Tuesday which makes a 24 cent price for candled and 20 for buying case count.

A local dealer in refering to eggs prices yesterday said:

"Ranchers have sold their laying hens, finding no profit in eggs at the high price of feed. It has been shown by reliable computations that there is only about 50 per cent of the number of laying hens this year that there was last."

BANKING BY MAIL.

The German-American Savings Bank has issued a neat little booklet printed in English and German, giving information that everyone ought to know in regard to savings accounts, and how to conduct them by mail. This bank is one of the strong institutions of the great Southwest with nearly 25,000 depositors. It is not necessary to make a personal visit to this bank in order to open an account. If you want this booklet just drop a postal card to department L, German-American Savings Bank, Los Angeles, mentioning the Cultivator and a copy will be sent you.

San Francisco Markets

SAN FRANCISCO, April 6, 1909.

Hay.

Arrivals for the past six days have amounted to 1985 tons, being quite a dropping off from the arrivals of last week. The result of this short receipt has been to strengthen the price of the higher and better grades of hay; the poorer, and particularly the medium grades, drag a little, and are somewhat slow to sell.

As the end of the season approaches, it becomes apparent that our supply will just barely fill out the demand for the season. Farmers in many sections of the state have baled up their loose hay, which they have been holding in outdoor stacks and piled in their barns, and sending it in to market.

The excellent weather we have had during the last month has stimulated trade in this city to a degree unknown since the Christmas holidays.

Banking reports, and reports from general business throughout the state of California are all on the improve, and all have a tendency to keep the market, particularly the hay market, in good strong condition.

MORE NEXT YEAR.

Chas. Hamburg, of the Whittier Nursery, has sold many grafted walnuts this year. They have given satisfaction and brought many commendations like the following from Messrs. Fred H. Young & Son of Filmore: "Trees came in fine shape, were well packed and well dug. Thanking you many times for the ten extra trees. Are all done planting, if nothing happens we will be in the market for more next year."

Citrus Market

LOS ANGELES, APRIL 7, 1909.

An average of over 200 cars of oranges are going forward daily and so far as can be determined the market is in such condition that it will absorb them at good prices. In fact the general condition the country over is excellent and with the two months in which navels will yet be marketed the feeling seems to be that all navels will be absorbed so as to give good returns to the growers. There are now about seven or eight thousand cars of navels yet to go. The seedlings and other varieties have also met with good sales and have gone forward in liberal quantities. Some growers who have been compelled to lighten their Valencia trees have also been forwarding Valencias. But the great bulk of that crop will not begin to move until well toward June. Even the auctions have given good returns and handled immense quantities of fruit.

Lemons are meeting with good reception notwithstanding large receipts of foreigns. If anything the market is much stronger and will continue satisfactory, if present indications can be trusted, through the entire summer.

Shipments.

Total shipments to date, since November 1st, aggregate 13,760 cars of oranges, 2,101 cars of lemons. To same date last season 14,082 cars or oranges and 1887 cars of lemons.

NEW YORK, April 5.—Thirty-two carloads navels, one carload bloods, one carload tangerines and two carloads lemons sold. Market very strong, higher, all grades and sizes of oranges. Weather clear, favorable.

THE MOISTURE LIMIT IN BUTTER.

Replying to an inquiry, Prof. E. H. Farrington of the University of Wisconsin explains that the per cent of water and the per cent of moisture in butter are the same thing. Some persons use the first term and others the second. The present law states that butter containing over 16 per cent water must pay a tax of 10 cents per pound, since it is classified as adulterated. It is quite necessary that butter makers be absolutely sure that the butter they are making does not exceed the 16 per cent limit.

For the benefit of those who have not the means of testing their product for percentage of moisture, Professor Farrington suggests that they need have no fear of exceeding the 16 per cent limit if they will wash the granules of butter with cold water at about 50 degrees F., allowing the butter to stand in this water until the granules become hard and firm. Then after draining off the water, wash and allow the butter to stand in the churn some time until it drains rather dry. Sprinkle the salt over this and give it the usual amount of working. Excessive moisture is held in butter that is soft and not thoroughly drained.

A NEW NOVEL BY DR. BRADY.

In the Woman's Home Companion for April is begun a stirring new novel by Cyrus Townsend Brady, entitled "Hearts and the Highway." The various instalments of the story are to be illustrated by F. C. Yohn. The Reverend Dr. Brady is a typically strenuous Amrican. In addition to writing popular and successful novels and lecturing he is a militant minister of the gospel. He has recently become rector of a large parish in Kansas City, Missouri.

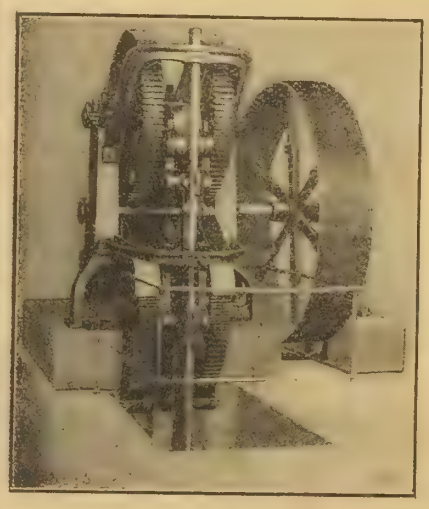
The Smooth Running, Noiseless Pomona Deep Well Pump



It is thirty to fifty per cent more efficient than any centrifugal pump ever made. No high speed bearings to cut out. All breakages and rod troubles eliminated.

This is the only pump you can afford to buy if you consider your own interests. Hundreds of satisfied users testify to this.

Used by the best water companies who know what a good pump is.

Send for a catalog or what is better come to POMONA and let us show you some of these plants in operation.

POMONA MANUFACTURING CO.
POMONA, CALIFORNIA

THE
Latest Deep Well

Guaranteed to deliver from 100 gallons per minute upwards, depending on the diameter and capacity of well, from a depth of 50 to 300 feet below the surface. Can be either belt driven or direct connected to electric motor as occasion requires.

Write for Catalogue 46B.

Byron Jackson Iron Works

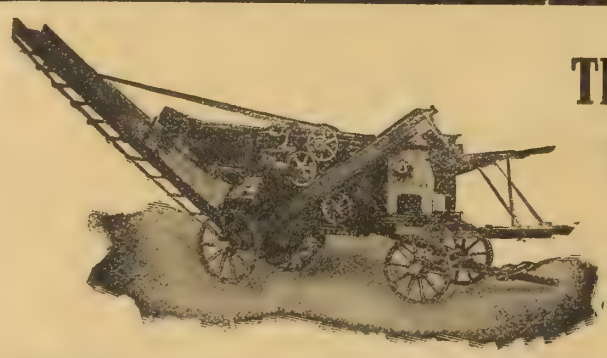
Turbine Pump

A deep well pump that has no valves or plungers to wear or get out of order, no gears, consequently no noise or breaking of teeth.

Compact, durable, always primed and ready to operate, constant flow, hence increased capacity of well.

This type of pump is fast taking the place of Vertical Steam, Deep well Plunger and Propeller Pumps.

Main Office and Works:
Carlton Station
West Berkeley, Cal.



A
Threshing Machine For The Farmer

That wants to do his own threshing—and not have to wait until the other fellow is ready to do it for you. More than pay for itself the first season. Guaranteed to thresh the grain clean. Can be operated with 4-H. P. sweep, steam or Gasoline Engine. Stock shipped from Sacramento. Write me for large descriptive circular, prices and terms.

GEO. W. FOOTT, 117 Grand Ave., Portland, Oregon

A LITTLE TALK on DISCS

We have often called attention to the fact that **Tubular Cream Separators** are entirely different from other cream separators, are in a different class, built on scientific principles; built to wear; built to skim clean; built to give general satisfaction; which means built without discs, and without the wabbling disc bowl, the difficulties in keeping the bowl in balance and the uncleanable, cream tainting features of the common disc bowl.

The Universal Prestige of Tubular Separators

is largely due to the entire absence of the objectionable features common to all disc separators, and this in connection with perfect mechanical construction, and exclusive conveniences found only in Tubular Separators, is sufficient reason for the sale of Tubulars so far exceeding those of any two competitors. IT'S THE NATURAL RESULT.

We Have Made This Statement Often

All "bucket bowl" or "disc" separators built by our numerous competitors, old and new, are in the same class; have the same characteristics, whether good or bad, and one is just about as bad as another. Now comes our old "disky" competitor and advertises a patent infringement suit against a catalogue house separator which has been built and sold for a number of years. Our old friend seems to have just discovered that we were right when we said the catalogue house disc separators were just the same as his disc separator. He now admits that the catalogue house separator is identical with his disky construction and asks the United States Circuit Court to make the other fellow stop building them and his agents stop selling them. Our old friend is in bad straits; he has worked every scheme imaginable to bolster up the reputation of his very common "disc" machine, he has gone the limit in questionable advertising, he has employed a small army of salesmen to bluff the game through, and now he has had to ask the Court to help him out of his trouble. The real trouble is that the farmer has found out what our disky friend now admits; the catalogue house separator is as good as the old disc separator and the farmer is wise enough to buy the one that he can buy the cheapest. Anybody can build a disc separator cheap, and if the farmer or dairyman is willing to endure the inconveniences of a disc separator he should buy one that is sold cheap. Several of the new disc separators are more modern, more convenient, and more satisfactory than the much advertised "old original" and sell for half the price. No wonder our old friend needs help.

If a farmer or dairyman appreciates convenience, safety, economy, durability, perfect skimming, easy running and freedom from repair bills he should buy a Tubular, **and that is what most farmers are doing.** For full information write for catalogue No. 260.

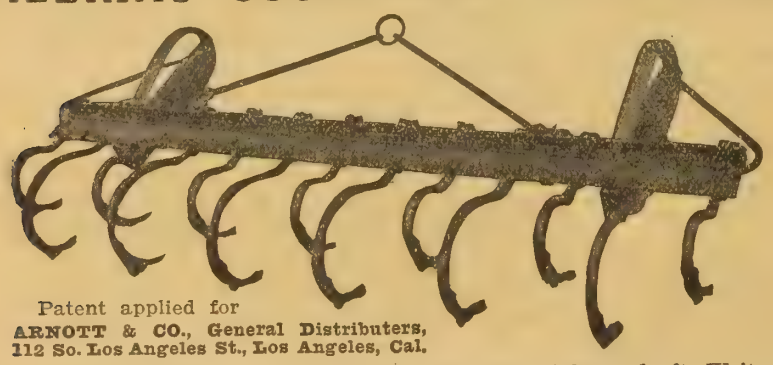
WILLIAMS' GOOSE-NECK CULTIVATOR



Patent applied for
ARNOTT & CO., General Distributers,
112 So. Los Angeles St., Los Angeles, Cal.

Especially adapted for citrus orchards. Sizes 7 to 14 ft. Lightest draft. Write today

The following is a sample of the unsolicited testimonials received regarding the Williams Goose-Neck Cultivator:

Merle, San Diego County, Cal., March 25, 1909.

Arnott & Company,
Los Angeles, California.

Dear Sirs:—You may recall that I recently purchased one of your Williams Goose-Neck Cultivators. I wish to say that I am exceedingly well pleased with it. In fact, as I told Mr. Jones, your representative in Oceanside, I would not take $500.00 for it if I could not get another. This is not an exaggerated statement, I mean it literally. In this section we do not have irrigation and everything depends on proper cultivation, so that good tools are very important. There are three points in which the Williams Goose-Neck Cultivator surpasses all other cultivators which I have seen, viz:

First. The draft is very light. My two horses weigh 900 lbs. each and they have no difficulty in drawing the 7 ft. cultivator.

Second. The Williams Goose-Neck Cultivator stirs the soil well without exposing the subsurface, thus preventing the escape of moisture.

Third. The cultivator being of low construction, one can cultivate under the trees as easily as harrow.

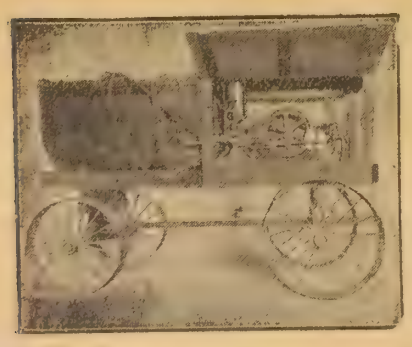
I was showing my cultivator to a neighbor the other day and had him take it home to try it. The use of it for half an hour so thoroughly convinced him of the merits of the tool that he has, through Mr. Jones of Oceanside, given you an order for one-half dozen cultivators.

Messrs. Williams & Son of Orange certainly deserve great credit for inventing the Goose-Neck Cultivator.

Sincerely yours

LOUIS C. LUHR.

WILLIAMS & SON, Mfrs., Orange, California



Olds Complete Power Spraying Outfit

Equipped with their air-cooled engine, which is a great advantage, making it much lighter and easier to operate. Send for circular and Price List 6802 to

Distribution of Water in the Soil

Report on Investigation of Furrow Irrigation Made by Prof. R. H. Loughridge of the State University and Issued by the Office of Experiment Stations

IRRIGATION is practiced more generally in the valleys of Southern California than in any other part of the state; and because of the low rainfall, the large area under culture, and the continually increasing number of citrus orchards the orchardists are realizing the importance of either a greater water supply or some means of utilizing better the amount on hand. An increase of the supply seems to be improbable, for apparently all the available local sources have been developed. A more economical use of the available supply is then the only way in which new orchards and new fields may be provided for without injury to those at present in bearing.

The question of economy resolves itself into the following: What amount of water should an orchard have for best productiveness? What becomes of the water that is given to an orchard under the present irrigation practice? How much is lost to the plant or tree, and how may this loss be stopped?

It was decided at the beginning of this investigation to confine the work to determining what becomes of the water when applied to the land. This embraces the amount lost by surface evaporation and the extent in area and depth to which the water percolates beneath the furrows, as well as the proportion retained by the soil or available to the trees.

The region of Riverside, in Southern California, was selected as the field of investigation because of the special interest manifested in the results by orange growers and because a leading land company generously gave the use of its orchards, together with every facility in the matter of water and in part the labor. We were ably assisted by Messrs. J. E. Roadhouse, O. W. Bryant, and R. McL. Fortier in the field work and in the compilation of results.

[We are told that "a leading land company" is the Arlington Heights Fruit Company of which Mr. James Mills is Superintendent. Also that the copy as written by Prof. Loughridge and sent to Washington contained due credit to Mr. Mills and his company. This was cut out in the office of experiment stations. This indicates a smallness of calibre which is surprising, but certainly can not be due to Director True, but doubtless to some under clerk. If a "Leading Land Company" gives service it is as worthy of credit as is the Division of Experiment Stations. Let the Division be big enough to divide up.—Ed.]

The furrow system of irrigation is used in the orchards around Riverside, some irrigators preferring five and others four furrows between tree rows. With five furrows the water is delivered to the land in greater volume and spreads laterally more rapidly and to a greater extent, and there is consequently a greater loss of evaporation.

Soil Moisture.

Water exists in the soil chiefly in two conditions, namely, hygroscopic and free, the former being that which is held as a thin film covering the surface of each grain of soil and not free to move except when vaporized by heat, while the free water is that which is free to move from place to place in soils, either by percolation under the influence of gravity or by capillarity under the influence of surface tension. The free water is alone to be regarded as of any value in promoting growth and productiveness, and in the following pages it alone is mentioned. Its movement is limited by the texture and water-holding power of the soil. The height to which it will rise above the source is controlled by the soil texture. The coarser the soil the less in height will water rise by capillarity. The depth of percolation for a given amount of water is limited by the water capacity and freedom of movement.

The soil beneath the furrows can be examined easily, and the results are often full of surprises for the irrigator. In some of the orange orchards in the regions of both Corona and Riverside it was found by examination that after a three days' run of the water it had reached a depth of only 10 or 12 inches, instead of several feet as it should have done.

Over 50 pages of details of the investigations are given of which the summary is:

Summary.
